ABSTRACT

We study issues concerning perturbative integrability of $\mathcal{N} = 6$ Chern-Simons theory at planar and weak 't Hooft coupling regime. By Feynman diagrammatics, we derive so called maximal-ranged interactions in the quantum dilatation generator, originating from homogeneous and inhomogeneous diagrams. These diagrams require proper regularization of not only ultraviolet but also infrared divergences. We first consider standard operator mixing method. We show that homogeneous diagrams are obtainable by recursive method to all orders. The method, however, is not easily extendable to inhomogeneous diagrams. We thus consider two-point function method and study both operator contents and spectrum of the quantum dilatation generator up to six loop orders. We show that, of two possible classes of operators, only one linear combination actually contributes. Curiously, this is exactly the same combination as in $\mathcal{N} = 4$ super Yang-Mills theory. We then study spectrum of anomalous dimension up to six loops. We find that the spectrum agrees perfectly with the prediction based on quantum integrability. In evaluating the six loop diagrams, we utilized remarkable integer-relation algorithm (PSLQ) developed by Ferguson, Bailey and Arno.

1 Introduction

The AdS/CFT correspondence[1] continues revealing remarkable relations between gauge and gravity theories. The most extensively studied so far is the correspondence between the four-dimensional $\mathcal{N} = 4$ superconformal Yang-Mills theory and the Type IIB superstring theory on $\text{AdS}_5 \times \mathbb{S}^5$ [1]. Importantly, both theories admit Lagrangian formulation, which involve two coupling parameters: the rank N of the gauge group G and the 't Hooft coupling constant λ for the former, and the string coupling g_s and the curvature scale R (as measured in string unit) for the latter. As such, perturbatively, one can compute physical observables in both theories in double series of the respective parameters and test the correspondence by comparing a given observable extracted from each sides. In the planar limit, $N \rightarrow \infty$ and $g_s \rightarrow 0$, remarkable agreement was discovered between the two sides for a variety of observables. The agreement is largely attributed to the integrability structure[2]-[17].

Recently, a Type IIA counterpart was discovered and added to the list of the AdS/CFT correspondence. The ABJ(M) theory is (2+1)-dimensional $\mathcal{N} = 6$ superconformal Chern-Simons theory and was proposed as the holographic dual to the Type IIA superstring theory on $\text{AdS}_4 \times \mathbb{CP}^3$ [18, 19]. A question of interest is whether the two sides in this Type IIA counterpart also have an integrability structure. Recently, positive indications toward the quantum integrability were accumulated[20]-[37]. At strong coupling side, Lax pair construction of the integrability was shown at leading order[20]. At weak coupling side, there were more indications. At two loops, spin chain Hamiltonian was computed explicitly for the $SO(6)$ subsector and was shown integrable[21, 22, 25]. See also Ref. [27]. At four loops, spectrum of the spin chain Hamiltonian was shown to agree with the prediction of the integrability[35, 36].

In this paper, we further continue our previous investigations [22, 25, 35] concerning integrability of the $\mathcal{N} = 6$ Chern-Simons theory in the weak 't Hooft coupling regime by computing the dilatation operator to six loops. Given that the integrability is in place up to four loops, why bother six loops? We contend that there are two important aspects that arise beginning at six loops and beyond: operator contents and recursive structure of the long-range spin chain. With these two issues on focus, we shall test the integrability of the $\mathcal{N} = 6$ Chern-Simons theory at six loop order. As in [35], we shall focus on magnon excitation in the $SU(2)$ subsector, compute operator structure *and* spectrum of the spin chain Hamiltonian up to six loops and check them against the prediction based on the integrability and the *centrally extended* $[\mathfrak{psu}(2|2) \oplus \mathfrak{psu}(2|2)] \ltimes \mathbb{R}^{2,1}$ superalgebra of excitation symmetry.

The off-shell $\mathfrak{psu}(2|2)$ superalgebra of the excitation symmetry is spanned by the two $su(2)$ rotation generators $\mathfrak{R}^a_b$, $\mathfrak{L}^\alpha_\beta$, the supersymmetry generator $\mathfrak{Q}^\alpha_a$ and the superconformal gener-

ator $\mathfrak{S}_\alpha^a$. The off-shell configuration is characterized by $sl(2, \mathbb{R})$ central charges $\mathfrak{C}, \mathfrak{K}, \mathfrak{K}^*$ [15]. Their (anti)commutators are given by [15]

$$\begin{aligned} [\mathfrak{K}_b^a, \mathfrak{J}^c] &= \delta_b^c \mathfrak{J}^a - \frac{1}{2} \delta_b^a \mathfrak{J}^c, \quad [\mathfrak{L}_\beta^\alpha, \mathfrak{J}^\gamma] = \delta_\beta^\gamma \mathfrak{J}^\alpha - \frac{1}{2} \delta_\beta^\alpha \mathfrak{J}^\gamma \\ \{\mathfrak{Q}_a^\alpha, \mathfrak{S}_\beta^b\} &= \delta_a^b \mathfrak{L}_\beta^\alpha + \delta_\beta^\alpha \mathfrak{K}_a^b + \delta_a^b \delta_\beta^\alpha \mathfrak{C} \\ \{\mathfrak{Q}_a^\alpha, \mathfrak{Q}_b^\beta\} &= \epsilon^{\alpha\beta} \epsilon_{ab} \mathfrak{K}, \quad \{\mathfrak{S}_\alpha^a, \mathfrak{S}_\beta^b\} = \epsilon_{\alpha\beta} \epsilon^{ab} \mathfrak{K}^*. \end{aligned} \quad (1.1)$$

The central charges $\mathfrak{C}$ is related to the energy by $E = \mathfrak{C}$, while $\mathfrak{K}, \mathfrak{K}^*$ introduced at off-shell are related to momentum of the magnon. Acting on a magnon transforming in the fundamental representation, closure of the superalgebra leads to the relation among the central charges

$$E^2 = \mathfrak{C}^2 = \frac{1}{4} + 4\mathfrak{K}\mathfrak{K}^*. \quad (1.2)$$

The central charges $\mathfrak{K}, \mathfrak{K}^*$ are in turn related to an excitation momentum P . More generally, a bound-state of Q elementary magnons transforming in higher-dimensional representations can be studied. The off-shell analysis was sufficient to determine the dispersion relation. It is

$$E(P) = \frac{1}{2} \sqrt{Q^2 + 16h^2(\lambda) \sin^2 \frac{P}{2}}, \quad (1.3)$$

where $h(\lambda)$ is a function of the 't Hooft coupling parameter λ .

Restricting to large N limit and $SO(6)$ sector of the $OSP(6|4, \mathbb{R})$ superconformal symmetry group, the quantum dilatation operator was computed explicitly at two loops from which an integrable alternating spin chain Hamiltonian and Bethe ansatz equations were identified [21, 22, 25]. Aspects of the integrability were explored further beyond two loops by focusing on diagrams generating *maximal-ranged* terms. These are the diagrams in which interaction vertices range over lattice sites of the spin chain Hamiltonian maximally. In [35], we computed four-loop contribution to these terms and found that the spectrum fits with the prediction based on the integrability and the excitation symmetry.

At each order in perturbation theory, depending on the range the 'spin' flavors at different sites are permuted, maximal-ranged terms in the dilatation operator are further classifiable into maximal-shuffling and next-to-maximal-shuffling terms. In $\mathcal{N} = 4$ SYM theory, it was found by Gross, Mikhailov and Roiban [3] that maximal-shuffling terms are computable recursively. Inspection of relevant Feynman diagrams indicates that all diagrams contributing to maximal-shuffling terms are related by a recursion relation and hence resumable to an exact all-order result. On the other hand, diagrams contributing to nonmaximal-shuffling terms are combinatorially too complicated to be resumable. One might anticipate that a similar argument exists for

the $\mathcal{N} = 6$ ABJ(M) theory since conformal interactions are tightly constrained by large amount of supersymmetry. Indeed, we shall find that the maximal-shuffling terms in the dilatation operator originates from the same class of skeleton diagrams which we call *homogeneous* diagrams. We were able to perform all-order resummation and show that they match with the structure of dilatation operator predicted by integrability. The nonmaximal-shuffling terms receive contribution from another class of skeleton diagrams which we call *inhomogeneous* diagrams. As these diagrams are not recursively resumable and afflicted with potential infrared divergences, we need to resort to an alternative approach for direct evaluation. In the second half of work, we thus adopt two-point function method and compute six-loop contribution to maximal-ranged interactions from both homogeneous and inhomogeneous diagrams. This method amounts in dual Type IIA string theory to deriving time evolution Hamiltonian of a single non-interacting string.

Key results of our work point to the followings. The dilatation operator at six loops are extractable free of infrared divergences from two-point correlation functions of gauge invariant operators, which was already utilized in our earlier study at four loops [35]. Moreover, the maximal-ranged interactions are consistent with the integrability and that, curiously, operator contents of the long-range spin chain Hamiltonian is identical to those of the $\mathcal{N} = 4$ super Yang-Mills theory, viz. Inozemtsev spin chain [38, 8].

This paper is organized as follows. We begin with description of the expected spectrum based on the integrability and prediction for the maximal shuffling coefficients to all orders. In section 3, we recapitulate all-loop computation of maximal shuffling terms in $\mathcal{N} = 4$ super Yang-Mills theory, obtained first by Gross, Mikhailov and Roiban in [3]. We then extend the method to $\mathcal{N} = 6$ Chern-Simons theory and find two classes of diagrams contributing to the maximal shuffling. The first class of diagrams, homogeneous diagrams, is computable by a straightforward extension of the method in [3] and yields a result exactly parallel to the $\mathcal{N} = 4$ super Yang-Mills theory. The second class, inhomogeneous diagrams, is not computable by the method of [3] or variants of it: these diagrams are afflicted with infrared divergences. We conclude that all-order derivation for the maximal shuffling part of the dilatation operator is not straightforward in $\mathcal{N} = 6$ Chern-Simons theory. We thus resort to computing operator contents and spectrum of their anomalous dimensions order by order in perturbation theory. In section 4, we study 6-loop contribution to the anomalous dimension directly defined by two point correlation functions of operators. In section 5, we identify the matrix structures of the homogeneous and the inhomogeneous maximal-ranged interactions at 6-loops. In section 6, we compute the maximal-ranged part of the 6-loop Hamiltonian and confirm the prediction based on the inte-

grability. We also show that only one particular choice arises among two possible maximal shuffling operators. This operator is the same as the one arising in the $\mathcal{N} = 4$ super Yang-Mills theory. In section 7, we extend our results to parity non-conserving $\mathcal{N} = 6$ ABJ theory, whose gauge group is $U(M) \times U(N)$ with $N < M < N + k$. The last section is devoted to the concluding remarks. In the appendices, we relegate several technical details. Appendix A illustrate a comparative calculation of inhomogeneous term in operator-mixing method. Appendix B presents several lattice operator identities. Appendix C discusses derivation of skeleton 4-loop diagrams. Appendix D explains implementation of numerical integration and the remarkable integer relation PSLQ algorithm.

2 Hamiltonian and Spectrum From Integrability

We begin with consequence of the quantum integrability and the off-shell superalgebra to the spin chain Hamiltonian of a sub-sector of our interest. Consider single-trace bosonic operators in the $\mathcal{N} = 6$ ABJM theory of the type

$$\Psi[I_1 I_2 I_3 I_4 I_5 \cdots I_{2L}] = \text{tr}[Y_{I_1} Y_{I_2}^\dagger Y_{I_3} Y_{I_4}^\dagger Y_{I_5} \cdots Y_{I_{2L}}^\dagger]. \quad (2.1)$$

Here, $2L$ is the total number of the sites. We shall take the infinite volume limit $L \rightarrow \infty$ and view a particular ordering of the operator as a lattice spin chain wave function Ψ . Gauge invariant operators place at odd sites the Y_I ($I, J = 1, 2, 3, 4$) elementary scalar fields transforming as **4** under the $SU(4)$ R-symmetry and at even sites the $Y_I^\dagger$ conjugate fields. Under the $SU(4) \simeq SO(6)$ R-symmetry, these fields transform as **4** and $\bar{\mathbf{4}}$, respectively. We denote $\{Y_1, Y_2, Y_3, Y_4\}$ as $\{A_1, A_2, B_1^\dagger, B_2^\dagger\}$ where $A_a, B_{\dot{a}}$ ($a, \dot{a} = 1, 2$) transform under the $SU(2)_A$ and the $SU(2)_B$ subgroups of $SU(4)$. We then consider a subset of the operators (2.1), where we put only $A_a / B_{\dot{a}}$ fields at the odd / even sites, respectively. Explicitly, they are the following restricted set of operators

$$\Psi[a_1 \dot{a}_2 a_3 \dot{a}_4 a_5 \cdots \dot{a}_{2L}] = \text{tr}[A_{a_1} B_{\dot{a}_2} A_{a_3} B_{\dot{a}_4} A_{a_5} \cdots B_{\dot{a}_{2L}}]. \quad (2.2)$$

Since the only possible interaction between Y_I and $Y^\dagger J$ fields is the contraction δ_I^J group theoretically, there cannot be any interaction between **4** and $\bar{\mathbf{4}}$ representations acting on the above type of states. Therefore, for this restricted set of operators, the odd-site chain and even-site chain are decoupled from each other. Thus, there will be *A*-type magnon and *B*-type magnon propagating independently without any interactions between them. For unrestricted operators, there are interactions between them, but the above choice avoids unnecessary complexity in investigating the integrability. For the reference vacuum, we take the ferromagnetic

state $|0\rangle = \Psi[111111 \cdots 1] = \text{tr}[A_1 B_1 A_1 B_1 A_1 \cdots B_1]$. In [35], we explained how elementary excitations above the reference vacuum are organized by the centrally extended $[psu(2|2) \oplus psu(2|2)] \ltimes \mathbb{R}^{2,1}$ superalgebra. The first $psu(2|2)$ acts on the flavors of the magnons formed by exciting odd sites of the spin chain, while the second $psu(2|2)$ acts on the magnons at even sites. The bosonic $su(2)$ subalgebra of $psu(2|2)$ superalgebra corresponds to exciting Y_2, Y_4 for the odd sites and $Y_2^\dagger, Y_4^\dagger$ for the even sites. In [35], we carried out careful study of the representations of the centrally extended superalgebra for the asymptotic spin chain where $2L$ is sent to infinity. The quantum integrability of the dilatation operator implies the factorization of multi-magnon S-matrices into product of two-magnon S-matrices satisfying the Yang-Baxter equations¹. For both the ABJM and the ABJ theories, we also showed [22, 25] that dynamics of the magnons on even sites and on odd sites are governed by two separate transfer matrices $\tau^{\text{alt}}(u, \gamma), \bar{\tau}^{\text{alt}}(v, -\gamma)$ for arbitrary spectral parameters u, v, γ and that, using the Yang-Baxter equations, they are mutually commuting

$$[\tau^{\text{alt}}(u, \gamma), \tau^{\text{alt}}(v, -\gamma)] = 0, \quad [\bar{\tau}^{\text{alt}}(u, \gamma), \bar{\tau}^{\text{alt}}(v, -\gamma)] = 0, \quad [\tau^{\text{alt}}(u, \gamma), \bar{\tau}^{\text{alt}}(v, -\gamma)] = 0. \quad (2.3)$$

Their moments are

$$Q_n = \partial_u^{n-1} \ln \tau^{\text{alt}}(u, \gamma) \Big|_{u=0} \quad \text{and} \quad \bar{Q}_n = \partial_v^{n-1} \ln \bar{\tau}^{\text{alt}}(v, -\gamma) \Big|_{v=0} \quad (n = 1, 2, \dots) \quad (2.4)$$

of which $Q_2 + \bar{Q}_2$ is proportional to the dilatation operator. They all depend on the spectral parameter γ – a nonzero value of γ is an indication that the dilatation operator and all other higher moments are not invariant under lattice parity transformation. We found in [22, 25] that $\gamma = 0$ not only for the ABJM theory but surprisingly also for the ABJ theory, which is parity non-conserving. From (2.4), it followed that there are two sets of mutually commuting, infinitely many conserved charges

$$[Q_m, Q_n] = 0, \quad [\bar{Q}_m, \bar{Q}_n] = 0, \quad [Q_m, \bar{Q}_n] = 0. \quad (2.5)$$

It was argued [37] that these mutually commuting conserved charges are responsible for reflectionless property of the S-matrix elements between a magnon on even sites and a magnon on odd sites.

Invariance of the S-matrices under the off-shell superalgebra transformations was crucial to fix the representation as well as the spectrum of elementary magnons. The analysis (recapitulated in the previous section) shows that the dispersion relation of an elementary magnon takes

¹The all-loop proposal of the Bethe ansatz and S-matrices of $\mathcal{N} = 6$ ABJM theory was put forward in Ref. [23].

the form (1.3) with $Q = 1$ and P is pseudo-momentum of the magnon and $h(\lambda)$ is an interpolating function of the 't Hooft coupling λ . In addition, the pseudo-momentum P that specifies the central charge and the magnon spectrum can also be a function of the lattice momentum p defined by translation in the spin chain. The functional form of the interpolating function $h(\lambda)$ and the pseudo-momentum $P(p)$ are not determinable by the symmetry alone and require extra inputs of explicit computations either of $\mathcal{N} = 6$ Chern-Simons theory at weak coupling or of string worldsheet sigma-model at strong coupling. In the previous work [35], we found that $P(p) = p$ holds up to four-loop order. In this work, we shall assume this as an input and proceed for computation of six-loops and beyond.

Perturbatively, the interpolating function $h^2(\lambda)$ is expandable as

$$h^2(\lambda) = \lambda^2 \left(1 + \sum_{\ell=1}^{\infty} h_{2\ell} \lambda^{2\ell} \right) = \lambda^2 (1 + h_2 \lambda^2 + h_4 \lambda^4 + \dots) \quad (2.6)$$

where, for the leading term, we use the result of the two-loop computation in [21, 22]. Recently, in [36], the next coefficient h_2 was computed to be $h_2 = 4\zeta(2) - 16$. Thus, in terms of the lattice momentum p , the magnon dispersion relation can be expanded as

$$\begin{aligned} E(p) &= \sum_{n=0}^{\infty} \lambda^{2n} \sum_{l=0}^n e_{2n,2l} \sin^{2l} \frac{p}{2} \\ &= \left(\frac{1}{2} \right) + \left(4 \sin^2 \frac{p}{2} \right) \lambda^2 + \left(4h_2 \sin^2 \frac{p}{2} - 16 \sin^4 \frac{p}{2} \right) \lambda^4 \\ &+ \left(e_{6,2} \sin^2 \frac{p}{2} + e_{6,4} \sin^4 \frac{p}{2} + e_{6,6} \sin^6 \frac{p}{2} \right) \lambda^6 + \dots \end{aligned} \quad (2.7)$$

Note that $e_{0,0} = 1/2$ corresponds to the classical scaling dimension of the elementary scalar fields $Y_2, Y_4, Y_2^\dagger, Y_4^\dagger$ and $e_{2n,0} = 0$ ($n > 0$) is required by one-third of the $\mathcal{N} = 6$ supersymmetry preserved by the ferromagnetic vacuum state.² The two-loop coefficient $e_{2,2} = 4$ was found by explicit computation in [21, 22]. The four-loop coefficient $e_{4,4} = -16$ was computed in [35], while $e_{4,2} = 4h_2$ was argued in [36].

²In Chern-Simons theory, the choice of regularization method is known to be a subtle issue. Detailed study in [22, 25] utilized the dimensional reduction and obtained $e_{2,0} = 0$ at two loops. This confirms that the dimension reduction is a gauge invariant and supersymmetric regulator at least up to two loop order. Whether the corresponding Ward identities are satisfied at higher loops is an open problem that needs to be checked. All higher loop diagrams involving gauge and ghost fields are afflicted by the problem but diagrams involving matter fields only are not. Our previous [35] and the present works deal only with Feynman diagrams of the latter type and hence are free from this open problem.

On the other hand the expected spectrum based on the quantum integrability and the off-shell superalgebra representation theory is expandable as

$$\begin{aligned}
E(p) &= \frac{1}{2} \sqrt{1 + 16 h^2(\lambda) \sin^2 \frac{p}{2}} \\
&= \frac{1}{2} + \left(4 \sin^2 \frac{p}{2}\right) \lambda^2 + \left(4 \sin^2 \frac{p}{2}\right) \left[h_2 - 4 \sin^2 \frac{p}{2}\right] \lambda^4 \\
&\quad + \left(4 \sin^2 \frac{p}{2}\right) \left[h_4 - 8 h_2 \sin^2 \frac{p}{2} + 32 \sin^4 \frac{p}{2}\right] \lambda^6 + \dots,
\end{aligned} \tag{2.8}$$

where we use the expansion for $h^2(\lambda)$ in (2.6). Note that the coefficients $e_{2n,2n}$ are fixed completely by the dispersion relation:

$$e_{2n,2n} = (-1)^{n+1} 4^n \frac{(2n-2)!}{(n-1)! n!}. \tag{2.9}$$

It is the coefficient of the term $(\sin^2 \frac{p}{2})^n = (2 - e^{ip} - e^{-ip})^n / 4^n$. Therefore, at order λ^{2n} of the perturbation theory, the coefficient of the eigenvalue $e^{\pm i p n}$ is uniquely fixed as

$$c_{2n} = -\frac{(2n-2)!}{(n-1)! n!}. \tag{2.10}$$

As we shall explain below graphically, $e^{\pm i p n}$ is the eigenvalue of the maximal-shuffling operator on the spin chain lattice. From this argument, we conclude that the coefficients of the maximal-shuffling operators are fixed by the assumption of the integrability and the representation theory of off-shell symmetry superalgebra. In this work, we shall explicitly compute these coefficients at six loops and compare with (2.10). It constitutes a nontrivial check of the quantum integrability of $\mathcal{N} = 6$ Chern-Simons theory.

To derive the spectrum, following [35], we use the lattice-momentum eigenstates of elementary magnon. For the A-spin magnon propagating on the odd-site chain, we have

$$|p\rangle_A = \sum_{\ell=0}^{L-1} e^{i\ell p} |\dots (2\ell+1)_{A_2} \dots\rangle \quad \text{and} \quad |p\rangle_B = \sum_{\ell=1}^L e^{i\ell p} |\dots (2\ell)_{B_2} \dots\rangle. \tag{2.11}$$

Here, $|\dots (2\ell+1)_{A_2} \dots\rangle$ refers that we put A_2 at the $2\ell+1$'s site while we put A_1 for the remaining odd-sites, and similarly for the even-site chain. Hence, for an elementary magnon state, we may consider two kinds of states $|p\rangle_A \otimes |0\rangle_B$ and $|0\rangle_A \otimes |p\rangle_B$. Below we shall focus on the odd-site chain as the odd-site and even-site chains behave independently for the above subset of magnon states we are interested in.

The corresponding integrable Hamiltonian at each order is well known for the above set of states³. Since the structure of the even chain is identical to the odd chain, it is sufficient to focus

³All order generalization to the full spin chain that takes account of $4-\bar{4}$ interactions would be extremely interesting.

on the odd-site chain only. The zeroth order spin chain Hamiltonian counts the classical scaling dimension of the spins:

$$H_0 = \frac{1}{2} \sum_{l=0}^L \mathbb{I}. \quad (2.12)$$

The two loop part of the Hamiltonian is given by [21, 22]

$$H_2 = 4 \sum_{\ell=0}^{L-1} \mathbb{O}_{2,2}^{2\ell} \quad \text{where} \quad \mathbb{O}_{2,2}^{2\ell} = \frac{1}{4} [\mathbb{I} - \mathbb{P}_{2\ell+1, 2\ell+3}] \quad (2.13)$$

and $\mathbb{P}$ is the permutation operator defined by $\mathbb{P}_{ab}^{cd} = \delta_a^d \delta_b^c$. We shall take the infinite volume limit, $L \rightarrow \infty$, and do not consider wrapping interactions. The corresponding 4-loop Hamiltonian can be identified as

$$H_4 = e_{4,2} \sum_{\ell=0}^{L-1} \mathbb{O}_{2,2}^{2\ell} + e_{4,4} \sum_{\ell=0}^{L-1} \mathbb{O}_{4,4}^{2\ell} \quad \text{where} \quad \mathbb{O}_{4,4}^{2\ell} = \frac{1}{16} \left[4(\mathbb{I} - \mathbb{P}_{2\ell+1, 2\ell+3}) - (\mathbb{I} - \mathbb{P}_{2\ell+1, 2\ell+5}) \right].$$

This parallels the analysis of the $\mathcal{N} = 4$ super Yang-Mills theory [4, 7, 9]. The 6-loop Hamiltonian can also be identified as

$$H_6 = e_{6,2} \sum_{\ell=0}^{L-1} \mathbb{O}_{2,2}^{2\ell} + e_{6,4} \sum_{\ell=0}^{L-1} \mathbb{O}_{4,4}^{2\ell} + e_{6,6} \sum_{\ell=0}^{L-1} \left[(1 - \kappa_6) \mathbb{O}_{6,6}^{2\ell} + \kappa_6 \tilde{\mathbb{O}}_{6,6}^{2\ell} \right]. \quad (2.14)$$

Here, κ_6 is an arbitrary coefficient. We thus see that a new feature arises beginning at six loop order. Up to four loops, candidate spin chain operators consistent with the quantum integrability are uniquely fixed. At 6-loops, operators consistent with the integrability are no longer unique: there are two commuting, mutually independent operators

$$\begin{aligned} \mathbb{O}_{6,6}^{2\ell} &= \frac{1}{64} \left[\mathbb{P}_{2\ell+1, 2\ell+5} \mathbb{P}_{2\ell+3, 2\ell+7} - \mathbb{P}_{2\ell+1, 2\ell+7} \mathbb{P}_{2\ell+3, 2\ell+5} \right. \\ &\quad \left. + 4 \mathbb{P}_{2\ell+1, 2\ell+5} - 14 \mathbb{P}_{2\ell+1, 2\ell+3} + 10 \mathbb{I} \right], \\ \tilde{\mathbb{O}}_{6,6}^{2\ell} &= \frac{1}{64} \left[(\mathbb{I} - \mathbb{P}_{2\ell+1, 2\ell+7}) - 6(\mathbb{I} - \mathbb{P}_{2\ell+1, 2\ell+5}) + 15(\mathbb{I} - \mathbb{P}_{2\ell+1, 2\ell+3}) \right]. \end{aligned} \quad (2.15)$$

Notice that these operator contents are identifiable with the Inozemtsev spin chain system [38, 8]. Acting on the momentum eigenstate $|p\rangle_A$ in (2.11), these operators are diagonalized with the *same* eigenvalue

$$\sum_{\ell=0}^{L-1} \mathbb{O}_{2n, 2n}^{2\ell} |p\rangle_A = \sum_{\ell=0}^{L-1} \tilde{\mathbb{O}}_{2n, 2n}^{2\ell} |p\rangle_A = \sin^{2n} \frac{p}{2} |p\rangle_A. \quad (2.16)$$

So, the operator content of the six-loop Hamiltonian is not determinable uniquely by probing a single magnon dispersion relation. On the other hand, the operators $\mathbb{O}_{6,6}$ and $\tilde{\mathbb{O}}_{6,6}$ are distinguishable by acting on a state containing two or more magnon excitations. Note that both of them include the maximal-shuffling operators that produce the eigenvalues $e^{\pm i n p}$. From the purely integrability point of view of the long-ranged Heisenberg spin chain, both operators are allowed and fit perfectly. Below, we shall approach this issue by computing relevant Feynman diagrams explicitly. We then determine the coefficient κ_6 and, from it, the operator contents of the spin chain Hamiltonian.

3 Recursive Method for Maximal-Ranged Interactions

We begin in this section with a recursive method, first put forward by Gross, Mikhailov and Roiban [3], of extracting maximal-shuffling terms among maximal-ranged interactions. We first redo the computation in $\mathcal{N} = 4$ super Yang-Mills theory and then repeat the computation in $\mathcal{N} = 6$ Chern-Simons theory.

Of maximal-ranged interactions, we are particularly interested in the coefficients c_{2n} of the maximal shuffling operators — they will provide a direct test of the integrability. In $\mathcal{N} = 4$ super Yang-Mills theory, Feynman diagrams contributing to maximal-shuffling term are easily identifiable. As will be briefly reviewed below, at each order in perturbation theory, there is only one type diagram contributing to maximal-shuffling term. We refer to it as *homogeneous* diagram. For example, at 3-loop order, this maximal-shuffling term is responsible for the operator $\mathbb{O}_{6,6}$. There are also non-maximal-shuffling terms generated from maximal-ranged diagrams.

For $\mathcal{N} = 6$ Chern-Simons theory, despite different interaction structures, we find a strikingly similar pattern repeated. Among the maximal-ranged interactions, maximal-shuffling term arises from homogeneous diagram. It turns out this diagram gives rise to the operator $\mathbb{O}_{6,6}$, as in the situation of the $\mathcal{N} = 6$ super Yang-Mills theory. We shall further confirm the coefficients c_{2n} of the maximal shuffling terms. Among the maximal-ranged interactions, there are also inhomogeneous diagrams that give rise to nonmaximal-shuffled terms. At six-loop order, for instance, these diagrams are responsible for the operator $\kappa_6 [\tilde{\mathbb{O}}_{6,6} - \mathbb{O}_{6,6}]$. However, by a direct computation, we shall find the coefficient κ_6 vanishes identically. This is interesting since, a priori, this operator could be generated given that interactions in the $\mathcal{N} = 6$ Chern-Simons theory are different from those in the $\mathcal{N} = 4$ super Yang-Mills theory, this operator could be generated.

3.1 $\mathcal{N} = 4$ super Yang-Mills theory

We first rederive the all-loop, maximal ranged interactions in $\mathcal{N} = 4$ super Yang-Mills theory obtained by Gross, Mikhailov and Roiban [3], emphasizing aspects directly relevant for similar considerations in $\mathcal{N} = 6$ Chern-Simons theory.

Figure 1: *Homogeneous diagram in maximal-ranged interactions in $\mathcal{N} = 4$ super Yang-Mills theory. It generate maximal-shuffling term in the dilatation operator.*

Consider in the $\mathcal{N} = 4$ super-Yang-Mills theory renormalization of composite operators. Introduce in the theory the dimensional regularization parameter ε , $d = 4 - 2\varepsilon$ of ultraviolet divergences. To avoid infrared divergences, a set of external momenta q are also injected to the operator. Denote by $I_{\text{bare}}(\varepsilon, q)$ a collection of regularized Feynman diagrams that contribute to the renormalization of composite operators of the type (2.1). Omitting wave function renormalization part proportional to the identity part, multiplicative renormalizability of the operators asserts that

$$I_{\text{ren}}(q) = \exp \left[\frac{1}{2\varepsilon} \int_0^1 \frac{dt}{t} \left(H_4(\lambda t) - 1 \right) \right] I_{\text{bare}}(\varepsilon, q) \quad (3.1)$$

ought to be finite in the limit where ε goes to zero. The generator $H_4(\lambda)$ is the quantum dilatation operator generating renormalization group transformation and its eigenvalue corresponds to the magnon dispersion relation in the spin chain interpretation. In perturbation theory,

$$I_{\text{bare}}(\varepsilon, q) = 1 + \sum_{\ell=1}^{\infty} I_{\text{bare}}^{(\ell)}(\varepsilon, q) . \quad (3.2)$$

From the ε -independence of $I_{\text{ren}}(k)$, we get the relation

$$\int_0^1 \frac{dt}{t} \left(H_4(\lambda t) - 1 \right) = - \lim_{\varepsilon \rightarrow 0} 2\varepsilon \ln I_{\text{bare}}(\varepsilon, q) , \quad (3.3)$$

for the operators which do not include the identity part. In planar $\mathcal{N} = 4$ super Yang-Mills theory, the maximal-ranged interactions are generated only by quartic scalar interactions. Homogeneous diagrams among them are depicted in Fig. 1. To avoid infrared divergences, we inject a finite momentum q to the X field from the right in Fig. 1. It suffices to keep zero momentum for all other Z fields. The ℓ -loop contribution to the maximal shuffling diagrams can be evaluated recursively from the $(\ell - 1)$ -loop contribution [3]:

$$I_{\text{bare}}^{(\ell)}(\epsilon, q) = \left(\frac{4\pi}{q^2} \right)^{\ell\epsilon} \frac{1}{\epsilon^\ell \ell!} \frac{[\Gamma(1-\epsilon)]^{\ell+1} \Gamma(1+\ell\epsilon)}{\Gamma(2-(\ell+1)\epsilon) \prod_{j=2}^{\ell} (1-j\epsilon)} \hat{a}^\ell, \quad (3.4)$$

where $\hat{a}$ denotes $\lambda (e^{ip} + e^{-ip} - 2)/(16\pi^2)$ and p denotes the lattice momentum such that $e^{\pm ip}$ generates shift one lattice site to the left or right in the spin chain. From the integrability, we expect the Hamiltonian to be

$$H_4(\lambda, p) = \sqrt{1-4\hat{a}} = \sqrt{1 - \frac{\lambda}{4\pi^2} (e^{ip} + e^{-ip} - 2)}. \quad (3.5)$$

One can check finiteness of the renormalized diagrams $I_{\text{ren}}(q)$ in (3.1) order by order in λ . For instance, we checked this explicitly to the order $O(\lambda^5)$ using the Mathematica and found that the renormalized diagrams to this order are indeed finite, canceling all ϵ^{-n} ($n > 0$) singular terms. As was done in [3], we now show asymptotically that the singular terms of the regularized amplitude $I_{\text{bare}}(\epsilon)$ are canceled by the expected Hamiltonian (3.5) in the renormalization factor

$$\exp \left[\frac{1}{2\epsilon} \int_0^1 \frac{dt}{t} (\sqrt{1-4\hat{a}t} - 1) \right] = \exp \left[\frac{1}{\epsilon} \left(\sqrt{1-4\hat{a}} - 1 + \ln \frac{2}{1+\sqrt{1-4\hat{a}}} \right) \right] \quad (3.6)$$

in the limit ϵ goes to zero. To show this, we take $\epsilon \rightarrow 0$ while holding $x := \ell\epsilon$ finite and sum the all-loop contribution by the Euler-McLaughlin formula:

$$\begin{aligned} I_{\text{bare}}(\epsilon, q) &= \sum_{\ell=0}^{\infty} I_{\text{bare}}^{(\ell)}(\epsilon, q) \\ &\simeq \frac{1}{\sqrt{\epsilon}} \int_0^{\infty} dx f_4(x, q) \exp \left[\frac{1}{\epsilon} \left(x(\ln \hat{a} - \ln x + 2) + (1-x) \ln(1-x) \right) \right]. \end{aligned} \quad (3.7)$$

We have relegated all sub-leading remainder to $f_4(x, q)$:

$$f_4(x, q) := \frac{1}{\sqrt{x}} e^{-\psi(1)x} \left(\frac{4\pi}{q^2} \right)^x \frac{\Gamma(1+x)}{\Gamma(2-x)}, \quad (3.8)$$

where $\psi(z)$ is the poly-gamma function. The integral can be evaluated by the saddle-point approximation. At the saddle-point

$$x_0 = \frac{1}{2} (1 - \sqrt{1-4\hat{a}}), \quad (3.9)$$

the integral is evaluated as

$$I_{\text{bare}}(\varepsilon, q) = \exp \left[-\frac{1}{\varepsilon} \left(\sqrt{1-4\hat{a}} - 1 + \ln \frac{2}{1+\sqrt{1-4\hat{a}}} \right) + R_4(q) \right]. \quad (3.10)$$

The ε^{-1} pole term is precisely inverse of the renormalization factor (3.6) dictated by the integrability. As it should be, the renormalization factor is independent of the infrared regularizing momentum q – the dependence resides in the finite remainder function $R_4(q)$.

Figure 2: *Inhomogeneous diagram in maximal-ranged interactions in $\mathcal{N} = 4$ super Yang-Mills theory. It generate nonmaximal-shuffling term in the dilatation operator. The circles mark presence of vertices none of whose legs are connected to the operator.*

Among the maximal-ranged interactions, there are also inhomogeneous diagrams. At four-loop order, they were studied in [34]. These diagrams are distinguished from homogeneous diagrams that some of the scalar quartic vertices do not connect to the operator at all. They are responsible for generating nonmaximal-shuffling terms in the dilatation operator. One can convince that these diagrams proliferate rapidly at higher orders in perturbation theory and, even worse, do not show any recursive pattern. Therefore, their contribution needs to be computed individually. In section 6, adopting two-point function method, we will find that the inhomogeneous diagrams can be computed without ambiguity.

3.2 $\mathcal{N} = 6$ Chern-Simons theory

We now extend the recursive method to $\mathcal{N} = 6$ Chern-Simons theory. One easily see that relevant Feynman diagrams are classifiable again into *homogeneous* and *inhomogeneous* diagrams. The homogeneous diagrams are planar irreducible diagrams all of whose interaction vertices are connected to the operator by two internal lines. The *inhomogeneous* diagrams: planar irreducible diagrams some of whose interaction vertices are connected to the operator by one internal line or not connected to the operator at all.

Here, we first consider the homogeneous diagrams as they are easier to evaluate. The ho-

Figure 3: ‘homogeneous’ maximal shuffling diagrams

homogeneous diagrams include all maximal shuffling terms. let us first state the expected scaling of operators via the anomalous dimension.

Here, as explained in detail in [22, 25], we adopt dimension reduction $2\omega = 3 - \epsilon$ for regularizing ultraviolet divergences in Feynman diagrams. To avoid infrared divergences, we again inject momenta q to the composite operator. Multiplicative renormalizability of composite operator asserts that

$$I_{\text{ren}}(q) = \exp \left[\frac{1}{2\epsilon} \int_0^1 \frac{dt}{t} \left(H_3(\lambda^2 t) - \frac{1}{2} \right) \right] I_{\text{bare}}(\epsilon, q) \quad (3.11)$$

is independent of the regulator ϵ . Recall that, in $\mathcal{N} = 6$ Chern-Simons theory, ultraviolet divergences arise only at even loops. So, in perturbation theory,

$$I_{\text{bare}}(\epsilon, q) = 1 + \sum_{\ell=1}^{\infty} I_{\text{bare}}^{(2\ell)}(\epsilon, q), \quad (3.12)$$

where $I_{\text{bare}}^{(2\ell)}(\epsilon, q)$ denotes the 2ℓ -loop regularized diagrams of order $O(\lambda^{2\ell})$. From ϵ -independence of $I_{\text{ren}}(q)$, we get the relation

$$\int_0^1 \frac{dt}{t} \left(H_3(\lambda^2 t) - \frac{1}{2} \right) = - \lim_{\epsilon \rightarrow 0} 2\epsilon \ln I_{\text{bare}}(\epsilon, q) \quad (3.13)$$

for the operators which do not include the identity part.

As we explained in the previous section, from the integrability, we expect that the Hamiltonian for the maximal shuffling term is given by

$$H_3(\lambda^2) = \frac{1}{2} \sqrt{1 - 4\hat{b}}. \quad (3.14)$$

Here, $\hat{b} = \lambda^2 (e^{ip} + e^{-ip} - 2)$ and $e^{\pm ip}$ should now be interpreted as a left/right shift operator by one lattice spacing on even- or odd-sites of the alternating spin chain. Therefore, the

integrability asserts that the renormalization factor is given by

$$\exp \left[\frac{1}{2\varepsilon} \int_0^1 \frac{dt}{t} \left(\frac{1}{2} \sqrt{1-4\hat{b}t} - \frac{1}{2} \right) \right] = \exp \left[\frac{1}{2\varepsilon} \left(\sqrt{1-4\hat{b}} - 1 + \ln \frac{2}{1 + \sqrt{1-4\hat{b}}} \right) \right]. \quad (3.15)$$

To check if ultraviolet divergence of the bare diagrams $I_{\text{bare}}(\varepsilon, q)$ is inverse of (3.15), we now evaluate the homogeneous diagrams. At elementary $2\ell + 2$ -loops, from Fig. 2, we see that the diagram can be evaluated using ℓ many skeleton propagators defined by 1-bubble diagram:

$$L_2(k) = \frac{C_2}{(k^2)^{2-\omega}} \quad \text{where} \quad C_2 = \frac{\Gamma^2(\omega-1)\Gamma(2-\omega)}{(4\pi)^\omega \Gamma(2\omega-2)}, \quad (3.16)$$

one skeleton propagator defined by 2-bubble diagram:

$$L_3(k) = \frac{C_3}{(k^2)^{3-2\omega}} \quad \text{where} \quad C_3 = \frac{\Gamma^3(\omega-1)\Gamma(3-2\omega)}{(4\pi)^{2\omega} \Gamma(3\omega-3)} \quad (3.17)$$

and using recursively the skeleton 1-loop integral:

$$\begin{aligned} G(a, b) &:= (4\pi)^\omega (p^2)^{a+b-\omega} \int \frac{d^{2\omega}k}{(2\pi)^{2\omega}} \frac{1}{(k^2)^a ((k+p)^2)^b} \\ &= \frac{\Gamma(a+b-\omega)}{\Gamma(a)\Gamma(b)} \frac{\Gamma(\omega-a)\Gamma(\omega-b)}{\Gamma(2\omega-a-b)}. \end{aligned} \quad (3.18)$$

Denote by $\mathcal{A}_\ell$ the coefficient that skeleton ℓ -loop contributes to the permutation $\mathbb{P}$ in the maximal-shuffling term $\mathcal{O} = 2\mathbb{I} - 4\mathbb{P}$ in the dilatation operator. Label n -th loop momenta by k_n and inject an external momentum q at the last skeleton vertex to regulate the loop integrals. At other vertices, there is no need to inject external momenta. Taking vertex and symmetry factors into account, the skeleton 0-loop (which is actually elementary 2-loop) contribution reads

$$\mathcal{A}_0(q) = (-(2\pi)^2) \cdot (-4) \frac{C_3}{(q^2)^{3-2\omega}}. \quad (3.19)$$

The skeleton 1-loop (which is actually elementary 4-loop) contribution reads

$$\begin{aligned} \mathcal{A}_1(q) &= (-(2\pi)^2)(-4) \int \frac{d^{2\omega}k_1}{(2\pi)^{2\omega}} \mathcal{A}_0(k_1) \frac{1}{k_1^2} \frac{C_2}{((k_1-q)^2)^{2-\omega}} \\ &= (-(2\pi)^2)^2 (-4)^2 G(4-2\omega, 2-\omega) \frac{C_2 C_3}{(4\pi)^\omega (q^2)^{2(3-2\omega)}}. \end{aligned} \quad (3.20)$$

The skeleton 2-loop (which is actually elementary 6-loop) contribution reads

$$\begin{aligned} \mathcal{A}_2(q) &= (-(2\pi)^2)(-4) \int \frac{d^{2\omega}k_2}{(2\pi)^{2\omega}} \mathcal{A}_1(k_2) \frac{1}{k_2^2} \frac{C_2}{((k_2-q)^2)^{2-\omega}} \\ &= (4\pi)^6 G(4-2\omega, 2-\omega) G(7-4\omega, 2-\omega) \frac{C_2^2 C_3}{(4\pi)^{2\omega} (q^2)^{3(3-2\omega)}}. \end{aligned} \quad (3.21)$$

Recursive pattern is evident. The skeleton ℓ -th loop (note that this is actually elementary $2\ell + 2$ -loop) contribution reads

$$\mathcal{A}_\ell(q) = \prod_{n=1}^{\ell} G(1+n(3-2\omega), 2-\omega) \cdot \frac{(4\pi)^{2\ell+2} C_2^\ell C_3}{(4\pi)^{\ell\omega} (q^2)^{(\ell+1)(3-2\omega)}}. \quad (3.22)$$

Multiplying $\hat{b}^{\ell+1}$ to $\mathcal{A}_\ell$, we find the regularized 2ℓ -loop amplitude has the expression

$$I_{\text{bare}}^{(2\ell)}(\varepsilon, q) = \left(\frac{4\pi}{q^2} \right)^{\ell\varepsilon} \frac{1}{\varepsilon^\ell \ell!} \frac{\left[\Gamma\left(\frac{1}{2} - \frac{\varepsilon}{2}\right) \right]^{2\ell+1} \Gamma(1+\ell\varepsilon)}{\Gamma\left(\frac{1}{2} - \frac{2\ell+1}{2}\varepsilon\right) \prod_{j=1}^{\ell} \left(\frac{1}{2} - \frac{2j+1}{2}\varepsilon\right)} \left[\frac{\hat{b}}{4\pi} \right]^\ell. \quad (3.23)$$

Using Mathematica, we checked up to 10-loop orders that the renormalized diagram $I_{\text{ren}}(q)$ in (3.11) with the H_3 dictated by the integrability is indeed finite in the limit where ε goes to zero.

As in the $\mathcal{N} = 4$ super Yang-Mills theory, we can estimate the asymptotic behavior of the bare diagram $I_{\text{bare}}(\varepsilon, q)$ in the limit $\ell \rightarrow \infty$, $\varepsilon \rightarrow 0$ while holding $x := \ell\varepsilon$ constant. By the Euler-McLaughlin formula, we have

$$I_{\text{bare}}(\varepsilon, q) \simeq \frac{1}{\sqrt{\varepsilon}} \int_0^\infty dx f_3(x, q) \exp \left[\frac{1}{2\varepsilon} \left(2x(\ln \hat{b} - \ln 2x + 2) + (1-2x) \ln(1-2x) \right) \right], \quad (3.24)$$

where $f_3(x)$ denotes a sub-dominant remainder

$$f_3(x, q) = \frac{1}{\sqrt{2x}} e^{-\psi(\frac{1}{2})x} \left(\frac{4\pi}{q^2} \right)^x \frac{\Gamma(1+x)}{\Gamma(\frac{1}{2}-x)}. \quad (3.25)$$

We evaluate the integral by the saddle-point approximation. At the saddle point:

$$x_0 = \frac{1}{4} (1 - \sqrt{1-4\hat{b}}), \quad (3.26)$$

the integral is given by

$$I_{\text{bare}}(\varepsilon, q) = \exp \left[-\frac{1}{2\varepsilon} \left(\sqrt{1-4\hat{b}} - 1 + \ln \frac{2}{1+\sqrt{1-4\hat{b}}} \right) + R_3(q) \right]. \quad (3.27)$$

We see that the ε^{-1} pole term is precisely the inverse of the renormalization factor in (3.15). It is remarkable that this all-loop agreement between the homogeneous diagrams and the integrability is closely parallel to the situation in the $\mathcal{N} = 4$ super Yang-Mills theory. Because of this, in the next section, we adopt the two-point function method for deriving quantum dilatation operator.

We also need to take account of inhomogeneous diagrams. It is easy to see that this class of diagrams does not include the maximal-shuffling terms. Nevertheless, the interaction range

Figure 4: ‘inhomogeneous’ maximal ranged diagrams

is still maximal, viz. maximal-ranged, at a given order in perturbation theory, as illustrated in Fig. 4. In so far as one just focuses on maximal-shuffling part the spectrum, the homogeneous diagrams are sufficient. If one would like to identify operator contents of the spin chain Hamiltonian, however, it is indispensable and crucial to take account of the inhomogeneous diagrams. For instance, at 6-loop order, the inhomogeneous diagrams are responsible for the coefficient κ_6 of the operator $\mathbb{O}_{6,6}^{\text{in}} = [\tilde{\mathbb{O}}_{6,6} - \mathbb{O}_{6,6}]$.

One would like to see if all-loop contribution of the inhomogeneous diagrams is also obtainable from the recursive method, much as for the homogeneous diagrams. Here, as in $\mathcal{N} = 4$ super Yang-Mills theory, the relevant diagrams proliferate rapidly at each higher order in perturbation theory and do not exhibit recursive pattern in any obvious way.

4 Anomalous dimension matrix

From now, as in the previous works [22, 25, 35], we shall extract the anomalous dimension matrix of the single-trace operators $\mathbb{O}$ of the type (2.1) from two-point correlation functions:

$$\langle : \mathbb{O}(x) : : \mathbb{O}(0) : \rangle_{\epsilon} = \frac{C_{\epsilon}^{2L}}{(x^2)^{\frac{1-\epsilon}{2} \cdot 2L} (x^2)^{\gamma(\epsilon)}} . \quad (4.1)$$

From the dual Type IIA string theory viewpoint, this method amounts to deriving time-evolution Hamiltonian of a single non-interacting string propagating in $\text{AdS}_4 \times \mathbb{CP}^3$ spacetime. We use the dimensional reduction to regularize ultraviolet divergences. The two-point correlation functions are related to Feynman loop diagrams $A_{2\ell}$ by

$$\begin{aligned} \langle : \mathbb{O}(x) : : \mathbb{O}(0) : \rangle_{\epsilon} &= (I_{\epsilon})^{2L} e^{-\gamma_{\epsilon} \ln(x^2 \Lambda^2(\epsilon))} \\ &= (I_{\epsilon})^{2L} \exp [\ln(1 + A_2 \lambda^2 + A_4 \lambda^4 + A_6 \lambda^6 \cdots)] , \end{aligned} \quad (4.2)$$

where I_ε denote the Euclidean scalar propagator in the position space

$$I_\varepsilon = \int \frac{d^{2\omega}p}{(2\pi)^{2\omega}} \frac{1}{p^2} e^{ip \cdot x} = \frac{\Gamma(\omega-1)}{4\pi^\omega} \frac{1}{(x^2)^{\omega-1}}. \quad (4.3)$$

Here we consider all Feynman diagrams, connected or not, contributing to a given order of $\lambda^{2\ell}$. As the definition of the anomalous dimension matrix takes the logarithm, it suffices to compute connected diagrams only. The anomalous dimension matrix is then extractable as coefficient of $\ln(x^2)$ in the exponent. Up to 6-loop orders, the spin chain Hamiltonians $H_{2\ell}$ classified in section 2 are given by

$$\begin{aligned} H_2 &= -\lim_{\varepsilon \rightarrow 0} \varepsilon A_2 \\ H_4 &= -\lim_{\varepsilon \rightarrow 0} 2\varepsilon \left[A_4 - \frac{1}{2} A_2^2 \right] \\ H_6 &= -\lim_{\varepsilon \rightarrow 0} 3\varepsilon \left[A_6 - \frac{1}{2} (A_2 A_4 + A_4 A_2) + \frac{1}{3} A_2^3 \right]. \end{aligned} \quad (4.4)$$

Note the extra factor n multiplied. It arises combinatorially from extracting coefficients of $\ln x^2$ from the 2ℓ -loop contribution $(\ln A)_{2\ell}$,

$$(\ln A)_{2\ell} = [c_{2\ell} \varepsilon^{-1} + O(\varepsilon^0)] (x^2)^{\ell\varepsilon} = [c_{2\ell} \varepsilon^{-1} + O(\varepsilon^0)] [1 + \ell\varepsilon \ln x^2 + O(\varepsilon^2)]. \quad (4.5)$$

At 2ℓ -loop order, we have

$$H_{2\ell} = -\ell \lim_{\varepsilon \rightarrow 0} \varepsilon (\ln A)_{2\ell}. \quad (4.6)$$

Summing over all loops,

$$H(\lambda^2) = \frac{1}{2} + \sum_{\ell=1}^{\infty} \lambda^{2\ell} H_{2\ell} \quad \text{and} \quad A(\varepsilon) = 1 + \sum_{\ell=1}^{\infty} \lambda^{2\ell} A_{2\ell}(\varepsilon) \quad (4.7)$$

and we have

$$\int_0^1 \frac{dt}{t} \left(H(\lambda^2 t) - \frac{1}{2} \right) = -\lim_{\varepsilon \rightarrow 0} \varepsilon \ln A(\varepsilon) = -\lim_{\varepsilon \rightarrow 0} 2\varepsilon \ln I_{\text{bare}}(\varepsilon). \quad (4.8)$$

Thus, starting from a different prescription, we have arrived at the same definition of the dilatation operator as (3.13). Here, the last equality followed from the fact that the $A(\varepsilon)$ is defined in terms of the two-point correlation function $\langle : \odot(x) : : \odot(0) : \rangle$, so is square of the $I_{\text{bare}}(\varepsilon)$ (equivalently, the $\ln A(\varepsilon)$ is twice of the $\ln I_{\text{bare}}(\varepsilon)$ connected diagrams) we considered in subsections 3.2 and 3.3.

Multiplicative renormalizability of the composite operators asserts that all ε^{-n} , ($n \geq 2$) singularities must cancel each other. We shall use such cancellations as a checkpoint of our computations. In A_2 , the contribution starts from ε^{-1} power and H_2 is automatically finite. In A_4 , leading singularity starts from ε^{-2} power. The coefficient of this singularity in $(\ln A)_4$ should vanish and the coefficient of order ε^{-1} leads to H_4 . In A_6 , there are in general singularities of ε^{-3} and ε^{-2} powers. The coefficients of them in $(\ln A)_6$ vanish and the coefficient of order ε^{-1} leads to H_6 . As discussed in Section 2, beginning at 6-loop orders, several independent spin chain operators can appear in H . The cancelation of higher-order singularities must then take place for the coefficients of each independent operators. At 6-loops, this will provide an additional stringent consistency check of our earlier 4-loop results [35] on whether computation of A_4 was correct and identification of spin chain operators was complete.

Figure 5: 6-loop homogeneous diagram involving maximal shuffling terms

Figure 6: adjoint of the above homogeneous diagram

5 Operator Contents of 6-Loop Dilatation Operator

We asserted earlier that, beginning at 6-loop order, the dilatation operator becomes complicated because there arise two types of maximally ranged interactions. In this section, we shall explain this in detail by analyzing operator contents of the 6-loop dilatation operator, focusing on the maximally ranged diagrams involving seven lattice sites.

Figure 7: 6 loop inhomogeneous diagram whose interactions are maximal-ranged

Figure 8: adjoint of the above inhomogeneous diagram

The first type of spin chain operator arises from the homogeneous diagrams and they give rise to the maximal shuffling terms. The diagrams in Figs. 5 and 6 belong to this category. The sextet interaction vertices are combined as in Figs. 5 and 6. The second type arises from the inhomogeneous diagrams. They are still maximally ranged but do not generate the maximal shuffling terms. Figs. 7 and 8 depict the inhomogeneous maximal ranged diagram at 6-loop order.

Their operator contents can be constructed from the basic building structure arising from the 2-loop sextet scalar vertices:

$$\begin{aligned} \mathbb{O}_{123}^{\ell} &= 2\mathbb{I} - \mathbb{K}_{\ell+1, \ell+2} - \mathbb{K}_{\ell+2, \ell+3} + 2\mathbb{P}_{\ell+1, \ell+3} \mathbb{K}_{\ell+1, \ell+2} \\ &+ 2\mathbb{P}_{\ell+1, \ell+3} \mathbb{K}_{\ell+2, \ell+3} - 4\mathbb{P}_{\ell+1, \ell+3}^2, \end{aligned} \quad (5.1)$$

where $\mathbb{K}_{ab}^{a'b'} = \delta_{ab} \delta^{a'b'}$ is the $\mathbf{4}-\bar{\mathbf{4}}$ covariant contraction operator. Here ℓ could be even or odd but, as mentioned before, we focus on the odd chain where ℓ is even. Acting this operator on the set of states in (2.2), all the terms involving the contraction operators drop out and the operator is reduced to

$$\mathbb{O}_{123}^{\ell} = 2\mathbb{I} - 4\mathbb{P}_{\ell+1, \ell+3}^2. \quad (5.2)$$

Below we shall present this reduced part only and omit all the contraction type operators. The

operator structure of the diagram in Fig. 5 is then

$$\mathbb{O}_{123}^\ell \mathbb{O}_{345}^\ell \mathbb{O}_{567}^\ell = 2^3 (\mathbb{I} - 2\mathbb{P}_{\ell+1, \ell+3}) (\mathbb{I} - 2\mathbb{P}_{\ell+3, \ell+5}) (\mathbb{I} - 2\mathbb{P}_{\ell+5, \ell+7}). \quad (5.3)$$

Similarly, the operator structure of Fig. 6 becomes

$$\mathbb{O}_{567}^\ell \mathbb{O}_{345}^\ell \mathbb{O}_{123}^\ell = 2^3 (\mathbb{I} - 2\mathbb{P}_{\ell+5, \ell+7}) (\mathbb{I} - 2\mathbb{P}_{\ell+3, \ell+5}) (\mathbb{I} - 2\mathbb{P}_{\ell+1, \ell+3}). \quad (5.4)$$

The numerical parts of these Feynman diagrams are the same. So, adding the two contributions, we obtain the spin chain operator

$$\mathbb{O}_{1\sim 7}^\ell = \mathbb{O}_{123}^\ell \mathbb{O}_{345}^\ell \mathbb{O}_{567}^\ell + \mathbb{O}_{567}^\ell \mathbb{O}_{345}^\ell \mathbb{O}_{123}^\ell. \quad (5.5)$$

One can show that this operator is related to the $\mathbb{O}_{6,6}^\ell$ by

$$\sum_\ell \mathbb{O}_{1\sim 7}^\ell = 64 \sum_\ell \left[64\mathbb{O}_{6,6}^\ell - 80\mathbb{O}_{4,4}^\ell + 22\mathbb{O}_{2,2}^\ell - \frac{1}{4}\mathbb{I} \right]. \quad (5.6)$$

The details of the derivation is relegated to appendix B. We focus on the maximally ranged interaction part only, and omit interactions of lower range given by $e_{6,2} \mathbb{O}_{2,2}$ and $e_{6,4} \mathbb{O}_{4,4}$. Thus, we conclude that the operator content of the homogeneous diagram is given by

$$\mathbb{O}_{1\sim 7}^\ell = 4^6 \mathbb{O}_{6,6}^\ell + \dots \quad (5.7)$$

where the ellipses denote the interactions of lower range.

The operator structure of the diagram in Fig. 7 is identified as

$$\mathbb{O}_{567}^\ell \mathbb{O}_{123}^\ell \mathbb{O}_{345}^\ell = 2^3 (\mathbb{I} - 2\mathbb{P}_{\ell+5, \ell+7}) (\mathbb{I} - 2\mathbb{P}_{\ell+1, \ell+3}) (\mathbb{I} - 2\mathbb{P}_{\ell+3, \ell+5}), \quad (5.8)$$

and that of the diagram in Fig. 8 as

$$\mathbb{O}_{345}^\ell \mathbb{O}_{123}^\ell \mathbb{O}_{567}^\ell = 2^3 (\mathbb{I} - 2\mathbb{P}_{\ell+3, \ell+5}) (\mathbb{I} - 2\mathbb{P}_{\ell+1, \ell+3}) (\mathbb{I} - 2\mathbb{P}_{\ell+5, \ell+7}). \quad (5.9)$$

Notice that the order the basic unit operators are multiplied is different from that in the homogeneous diagrams. Again, the numerical parts of these Feynman diagrams are the same. Combining them together, we obtain

$$\tilde{\mathbb{O}}_{1\sim 7}^\ell = \mathbb{O}_{567}^\ell \mathbb{O}_{123}^\ell \mathbb{O}_{345}^\ell + \mathbb{O}_{345}^\ell \mathbb{O}_{123}^\ell \mathbb{O}_{567}^\ell. \quad (5.10)$$

In appendix B, we show that

$$\begin{aligned} \tilde{\mathbb{O}}_{1\sim 7}^\ell &= -\mathbb{O}_{1\sim 7}^\ell - 64\mathbb{P}_{\ell+1, \ell+7} + 32\mathbb{I} \\ &= -\mathbb{O}_{1\sim 7}^\ell + 64 \left[64\tilde{\mathbb{O}}_{6,6}^\ell - 96\mathbb{O}_{4,4}^\ell + 36\mathbb{O}_{2,2}^\ell - \frac{1}{2}\mathbb{I} \right]. \end{aligned} \quad (5.11)$$

Hence, we have

$$\tilde{\mathbb{O}}_{1\sim 7}^\ell = 4^6 [-\mathbb{O}_{6,6}^\ell + \tilde{\mathbb{O}}_{6,6}^\ell] + \dots \quad (5.12)$$

where ellipses denotes the interactions of shorter range given by $e_{6,2} \mathbb{O}_{2,2}$ and $e_{6,4} \mathbb{O}_{4,4}$.

For completeness, we review the operator structures arising in the 4-loop maximally ranged interactions. For the 4-loop order, only diagrams of homogeneous type are present. These Feynman diagrams are depicted in Fig. 9 and Fig. 10. The numerical parts of the 4-loop amplitudes in Figs. 9 and 10 are the same. Combining them, we have the spin chain operator

$$\begin{aligned} \mathbb{O}_{1\sim 5}^\ell &= \mathbb{O}_{123}^\ell \mathbb{O}_{345}^\ell + \mathbb{O}_{345}^\ell \mathbb{O}_{123}^\ell \\ &= 16 \left[\frac{1}{2} \mathbb{I} - \mathbb{P}_{\ell+1, \ell+3} - \mathbb{P}_{\ell+3, \ell+5} + \mathbb{P}_{\ell+1, \ell+3} \mathbb{P}_{\ell+3, \ell+5} + \mathbb{P}_{\ell+3, \ell+5} \mathbb{P}_{\ell+1, \ell+3} \right]. \end{aligned} \quad (5.13)$$

This can be rewritten as

$$\mathbb{O}_{1\sim 5}^\ell = 16 \mathbb{P}_{\ell+1, \ell+5} - 8 \mathbb{I}, \quad (5.14)$$

where we again omit the contraction type operators. Here, we used the identity

$$\epsilon_{I a_1 a_3 a_5} \epsilon_{I b_1 b_3 b_5} = \mathbb{I} + \mathbb{P}_{13} \mathbb{P}_{35} + \mathbb{P}_{35} \mathbb{P}_{13} - \mathbb{P}_{13} - \mathbb{P}_{35} - \mathbb{P}_{15} = 0, \quad (5.15)$$

taking account of the fact that a_ℓ and b_ℓ are running over only $\{1, 2\}$.

6 Computation in the 6-Loop Dilatation Operator

In this section, we shall compute maximal-ranged interactions in the 6-loop dilatation operator (4.4) and extract the coefficients $e_{6,6}$ and κ_6 . As explained in the previous section, it suffices to compute the 6-loop maximally ranged operators, $\mathbb{O}_{6,6}$ and $\tilde{\mathbb{O}}_{6,6}$.

The first contribution to the maximal-range interactions arise from the A_2^3 part. The relevant 2-loop amplitude in Fig. 11 is organized as follows:

$$A_2 = a_2(\varepsilon) (x^2\pi)^{3-2\omega} \left[\cdots + \mathbb{O}_{123}^\ell + \mathbb{O}_{345}^\ell + \mathbb{O}_{567}^\ell + \cdots \right]. \quad (6.1)$$

In Ref. [35], the numerical coefficient $a_2(\varepsilon)$ was obtained as

$$\begin{aligned} a_2(\varepsilon) &= -\frac{[\Gamma(\omega-1)]^3 [\Gamma(3-2\omega)]^2 \Gamma(5\omega-6)}{16\pi [\Gamma(3\omega-3)]^2 \Gamma(6-4\omega)} \\ &= -\frac{1}{4\varepsilon} \left[1 + \left(1 - \psi\left(\frac{1}{2}\right)\right)\varepsilon + \frac{1}{24} \left(11\pi^2 + 12\psi^2\left(\frac{1}{2}\right) - 24\psi\left(\frac{1}{2}\right) - 72\right)\varepsilon^2 + O(\varepsilon^3) \right], \end{aligned} \quad (6.2)$$

where the poly-gamma functions take the value $\psi(\frac{1}{2}) = -\mathbf{C} - 2\ln 2$ and $\psi(1) = -\mathbf{C}$ with $\mathbf{C}$ ($= 0.577215\cdots$) being the Euler's constant. From this, we extract contribution of the A_2^3 to the relevant maximal-ranged interactions as

$$A_2^3 = (a_2(\varepsilon))^3 (x^2\pi)^{9-6\omega} \left[\cdots + \mathbb{O}_{1\sim 7}^\ell + 2\tilde{\mathbb{O}}_{1\sim 7}^\ell + \cdots \right], \quad (6.3)$$

where we already omit all disconnected contributions.

Figure 11: 2-loop diagram involving three sites

The $(A_2 A_4 + A_4 A_2)$ part is another contribution to the maximal ranged interactions. The relevant 4-loop contribution to the maximal-ranged interactions has the structure

$$A_4 = (x^2\pi)^{6-4\omega} \left[\cdots + a_4(\varepsilon) [\mathbb{O}_{1\sim 5}^\ell + \tilde{\mathbb{O}}_{3\sim 7}^\ell] + a_2^2(\varepsilon) \mathbb{O}_{123}^\ell \mathbb{O}_{567}^\ell + \cdots \right]. \quad (6.4)$$

This along with (6.1) gives rise to six loop maximal-ranged interactions through $(A_2 A_4 + A_4 A_2)$. We find

$$A_2 A_4 + A_4 A_2 = (x^2\pi)^{9-6\omega} \left[\cdots + 2a_2(\varepsilon) a_4(\varepsilon) [\mathbb{O}_{1\sim 7}^\ell + \tilde{\mathbb{O}}_{1\sim 7}^\ell] + a_2^3(\varepsilon) \tilde{\mathbb{O}}_{1\sim 7}^\ell + \cdots \right]. \quad (6.5)$$

Lastly, as discussed before, the relevant maximal-range interactions in A_6 are given by

$$A_6 = (x^2\pi)^{9-6\omega} \left[\cdots + a_6(\epsilon) \mathbb{O}_{1\sim 7}^\ell + \tilde{a}_6(\epsilon) \tilde{\mathbb{O}}_{1\sim 7}^\ell + \cdots \right]. \quad (6.6)$$

Using (4.4), we found that the coefficients of the maximal-ranged operators in $(\ln A)_6$ has the structure

$$\begin{aligned} (\ln A)_6 &= \left[a_6(\epsilon) - a_2(\epsilon)a_4(\epsilon) + \frac{1}{3}a_2^3(\epsilon) \right] \mathbb{O}_{1\sim 7} \\ &+ \left[\tilde{a}_6(\epsilon) - a_2(\epsilon)a_4(\epsilon) + \frac{1}{6}a_2^3(\epsilon) \right] \tilde{\mathbb{O}}_{1\sim 7} + \cdots. \end{aligned} \quad (6.7)$$

The 4-loop coefficient $a_4(\epsilon)$ was determined in [35]

$$a_4(\epsilon) = J_1(\epsilon) \cdot \frac{[\Gamma(\omega-1)]^5}{4^4\pi^2} \left[\frac{\Gamma(2-\omega)\Gamma(3-2\omega)}{\Gamma(2\omega-2)\Gamma(3\omega-3)} \right]^2 \cdot \frac{\Gamma(9\omega-11)}{\Gamma(11-8\omega)}. \quad (6.8)$$

The integral $J_1(\epsilon)$ is introduced by the following skeleton 2-loop integral K_5 :

$$\begin{aligned} K_5(w_1, w_2, w_3, w_4, w_5) &= (4\pi)^{2\omega} (p^2)^{-2\omega + \sum_{k=1}^5 w_k} \int \frac{d^{2\omega}k}{(2\pi)^{2\omega}} \frac{d^{2\omega}l}{(2\pi)^{2\omega}} \frac{1}{(k^2)^{w_1} (l^2)^{w_2}} \\ &\otimes \frac{1}{[(l-p)^2]^{w_3} [(k-p)^2]^{w_4} [(k-l)^2]^{w_5}}. \end{aligned} \quad (6.9)$$

The corresponding skeleton 2-loop integral is depicted in Fig. 12. As we evaluate the two-point correlation functions in the x space, we first evaluate the skeleton graph with nonvanishing momentum injected from the left to the right and then Fourier transform it back to the x -space. See Ref. [35] for the details of the method. The integral $J_1(\epsilon)$ evaluated from the skeleton 2-loop

Figure 12: The left is a skeleton 2-loop diagram used to evaluate A_4 . The skeleton 4-loop diagram on the right is for A_6 . We inject a momentum p following the arrows in each diagram.

integral K_5 :

$$J_1(\epsilon) \equiv K_5(2-\omega, 3-2\omega, 2-\omega, 3-2\omega, 1). \quad (6.10)$$

This integral is already nontrivial and does not allow analytic evaluation. Here we evaluated it numerically by using a Mathematica package. We took the strategy of expanding the integral $J_1(\epsilon)$ in powers of ϵ and determine term by term. The result is

$$\begin{aligned} J_1(\epsilon) &\equiv \frac{\alpha_{J_1}^{-1}}{\epsilon} \left[1 + \alpha_{J_1}^0 \epsilon + \alpha_{J_1}^1 \epsilon^2 + \dots \right] \\ &= -\frac{2}{3\pi\epsilon} \left[1 + \left(13 + \psi\left(\frac{1}{2}\right) \right) \epsilon + \left(488 - \frac{17}{2}\pi^2 + 52\psi\left(\frac{1}{2}\right) + 2\psi^2\left(\frac{1}{2}\right) \right) \frac{\epsilon^2}{4} + \dots \right]. \end{aligned} \quad (6.11)$$

We computed the leading coefficient $\alpha_{J_1}^{-1}$ numerically and matched to the above rational value. This is the value required for the multiplicative renormalizability of composite operator at four loops. The second coefficient is the one relevant for the 4-loop amplitude $\alpha_{J_1}^0$. Here, we checked this against the requirement of the multiplicative renormalizability at six loops. We computed the last coefficient $\alpha_{J_1}^1$ numerically up to 30 significant digits. We match this number as a linear combination of 1 and transcendental numbers π^2 , $\psi(\frac{1}{2})$, $\psi^2(\frac{1}{2})$ with the requirement that the coefficients are rational numbers. This is highly nontrivial to check. However, utilizing the remarkable algorithm PSLQ discovered recently by Ferguson, Bailey and Arno, we determined the combination in (6.11) as the unique solution. The details are explained in appendix D. Using this, we found that $a_4(\epsilon)$ has the series expansion

$$a_4(\epsilon) = \frac{1}{32\epsilon^2} \left[1 + \left(3 - 2\psi\left(\frac{1}{2}\right) \right) \epsilon + \left(-2 + \frac{11}{12}\pi^2 + 2\psi^2\left(\frac{1}{2}\right) - 6\psi\left(\frac{1}{2}\right) \right) \epsilon^2 + \dots \right]. \quad (6.12)$$

We now turn to the 6-loop coefficients $a_6(\epsilon)$ and $\tilde{a}_6(\epsilon)$. Consider first the coefficients arising from the diagrams in Figs. 5 and 6. One can easily verify that these two coefficients are the same. As explained in appendix C, we find

$$a_6(\epsilon) = -\frac{J_4(\epsilon)}{4^6\pi^3} \frac{[\Gamma(\omega-1)]^7 [\Gamma(2-\omega)]^4 [\Gamma(3-2\omega)]^2 \Gamma(13\omega-16)}{[\Gamma(2\omega-2)]^4 [\Gamma(3\omega-3)]^2 \Gamma(16-12\omega)}. \quad (6.13)$$

The Feynman integral can be reduced analytically to the function $J_4(\epsilon)$. Consider the skeleton 4-loop integral defined by

$$\begin{aligned} K_8(w_1 \cdots w_8) &\equiv (4\pi)^{4\omega} (p^2)^{-4\omega + \sum_{k=1}^8 w_k} \int \frac{d^{2\omega}k_1}{(2\pi)^{2\omega}} \frac{d^{2\omega}k_2}{(2\pi)^{2\omega}} \frac{d^{2\omega}k_3}{(2\pi)^{2\omega}} \frac{d^{2\omega}k_4}{(2\pi)^{2\omega}} \\ &\quad \otimes \frac{1}{(k_1^2)^{w_1} (k_2^2)^{w_2} (k_3^2)^{w_3} (k_4^2)^{w_4} [(k_1+k_2-p)^2]^{w_5}} \\ &\quad \otimes \frac{1}{[(k_3+k_4-p)^2]^{w_6} [(k_1-k_3)^2]^{w_7} [(k_2-k_4)^2]^{w_8}} \end{aligned} \quad (6.14)$$

Then the function $J_4(\varepsilon)$ is given by

$$J_4(\varepsilon) = K_8(2 - \omega, 3 - 2\omega, 3 - 2\omega, 2 - \omega, 2 - \omega, 2 - \omega, 1, 1, 1). \quad (6.15)$$

By using the PSLQ algorithm again, we determined that the function $J_4(\varepsilon)$ has the expansion in powers of ε as

$$\begin{aligned} J_4(\varepsilon) = & \frac{16}{135\pi^2\varepsilon^2} \left[1 + \left(28 + \frac{14}{15} + 2\psi\left(\frac{1}{2}\right) \right) \varepsilon \right. \\ & \left. + \left(522 - \frac{11}{25} - \frac{2}{9} - \frac{27}{2}\pi^2 + \frac{868}{15}\psi\left(\frac{1}{2}\right) + 2\psi^2\left(\frac{1}{2}\right) \right) \varepsilon^2 \right]. \end{aligned} \quad (6.16)$$

The coefficients of the first two terms fit precisely to the values required for the multiplicative renormalizability. As presented in appendix D, we checked numerically the first coefficient up to 14 significant digits and the second up to 9 significant digits. From the expansion (6.16), we found that $a_6(\varepsilon)$ is given by

$$a_6(\varepsilon) = -\frac{1}{384\varepsilon^3} \left[1 + 3 \cdot \left(2 - \psi\left(\frac{1}{2}\right) \right) \varepsilon + \left(\frac{80}{9} + \frac{11}{9}\pi^2 + 4\psi^2\left(\frac{1}{2}\right) - 16\psi\left(\frac{1}{2}\right) \right) \varepsilon^2 \right]. \quad (6.17)$$

Adding all pertinent contributions to $\mathbb{O}_{6,6}^\ell$, we get

$$a_6(\varepsilon) - a_2(\varepsilon)a_4(\varepsilon) + \frac{1}{3}a_2^3(\varepsilon) = -\frac{1}{96\varepsilon} + O(\varepsilon^0). \quad (6.18)$$

Contributions to the ε^{-3} and ε^{-2} terms cancel out, thus satisfying the consistency of multiplicative renormalizability. From (4.4) and (5.7), we finally determined the coefficient of $\mathbb{O}_{6,6}^\ell$ as

$$e_{6,6} = 128. \quad (6.19)$$

This is the value that agrees exactly with the prediction of the integrability.

Similarly, the coefficient $\tilde{a}_6(\varepsilon)$ in (6.6) arises from the diagrams in Figs. 7 and 8. As explained in appendix C, we find

$$\tilde{a}_6(\varepsilon) = -\frac{J_5(\varepsilon)}{4^6\pi^3} \frac{[\Gamma(\omega-1)]^6 [\Gamma(2-\omega)]^2 [\Gamma(3-2\omega)]^3 \Gamma(13\omega-16)}{[\Gamma(2\omega-2)]^2 [\Gamma(3\omega-3)]^3 \Gamma(16-12\omega)}, \quad (6.20)$$

where the function $J_5(\varepsilon)$ is the skeleton 4-loop integral:

$$J_5(\varepsilon) = K_8(2 - \omega, 2 - \omega, 3 - 2\omega, 3 - 2\omega, 3 - 2\omega, 1, 1, 1, 1). \quad (6.21)$$

Again, utilizing the PSLQ algorithm, we computed the series expansion of $J_5(\varepsilon)$ as

$$\begin{aligned} J_5(\varepsilon) = & \frac{16}{135\varepsilon} \left[1 + \left(19 + \frac{14}{15} + \frac{9}{2} + \psi(1) + \psi\left(\frac{1}{2}\right) \right) \varepsilon \right. \\ & \left. + \left(\frac{177587}{225} - \frac{61}{6}\pi^2 + \frac{733}{15} [\psi(1) + \psi\left(\frac{1}{2}\right)] + [\psi(1) + \psi\left(\frac{1}{2}\right)]^2 \right) \frac{\varepsilon^2}{2} + \dots \right]. \end{aligned} \quad (6.22)$$

We confirmed that the first two coefficients are the values required by the multiplicative renormalizability. See appendix D. We then obtained the coefficient $\tilde{a}_6(\varepsilon)$ in ε expansion as

$$\tilde{a}_6(\varepsilon) = -\frac{1}{192\varepsilon^3} \left[1 + \left(\frac{9}{2} - 3\psi\left(\frac{1}{2}\right) \right) \varepsilon + \left(\frac{11}{8}\pi^2 + \frac{9}{2}\psi^2\left(\frac{1}{2}\right) - \frac{27}{2}\psi\left(\frac{1}{2}\right) \right) \varepsilon^2 + \cdots \right]. \quad (6.23)$$

From this, we find the pertinent contribution to $\tilde{O}_{6,6}^\ell$ as

$$\tilde{a}_6(\varepsilon) - a_2(\varepsilon)a_4(\varepsilon) + \frac{1}{6}a_2^3(\varepsilon) = 0 \cdot \frac{1}{\varepsilon} + O(\varepsilon^0). \quad (6.24)$$

Again the coefficients of ε^{-3} and ε^{-2} are vanishing, which is the requirement of the renormalizability. From (4.4) and (5.12), we finally find that

$$\kappa_6 = 0. \quad (6.25)$$

As such, we conclude the operator $\tilde{\mathcal{O}}_{6,6}$, even though the integrability and the excitation symmetry allow it to be present, does not contribute to the 6-loop dilatation operator. Curiously, this parallels exactly to the structure of the dilatation operator in $\mathcal{N} = 4$ super Yang-Mills theory [8] — in both theories, the maximally-ranged interactions are governed by a single spin chain operator.

Summarizing, we determined uniquely the operator contents and the recursive structure of the 6-loop dilatation operator given by

$$H_6 = 128 \sum_{\ell} \mathbb{O}_{6,6}^\ell + \cdots, \quad (6.26)$$

where the ellipses denotes shorter-ranged terms we omitted.

7 Remarks on ABJ Theory

Up to this point, we focused, among the $\mathcal{N} = 6$ Chern-Simons theory, on the ABJM theory. This theory has the gauge group $U(N) \times U(N)$, the Chern-Simons coefficients $+k, -k$ and is invariant under parity. Notice that the parity is generalized to interchange the two gauge groups and hence all matter fields and their conjugates.

We can extend straightforwardly our considerations to the ABJ theory, which has the gauge group $U(M) \times U(N)$, the Chern-Simons coefficients $+k, -k$ but with $N < M < N + k$. This theory then breaks the generalized parity. As explained in [25] and recapitulated in section 2, the integrability and the Yang-Baxter equations therein implied that the dilatation operator is in general parity non-conserving. Nevertheless, explicit computations in [25, 35] showed that the

dilatation operator sustains to be parity conserving. At 6-loop order and beyond, as there begins to arise two types of spin chain operators in the dilatation operator, it becomes interesting if they source a room for parity (non)conservation beginning at this order.

From the Feynman diagrammatics, however, it is evident that all the changes in 6-loop diagrams of the ABJ theory compared to those in the ABJM theory is rather trivial; one just replaces the 't Hooft coupling-squared λ^2 of the ABJM theory by the product of two 't Hooft couplings $\lambda\bar{\lambda}$ of the ABJ theory. The nullification result $\kappa_6 = 0$ in (6.25) of the ABJM theory was *not* sensitive to the 't Hooft coupling as its dependence is an overall weighting factor. In the ABJ theory, by repeating the color factor counting in the Feynman diagrams, we find that all the contributing diagrams have the common dependence on M and N . Therefore, $\kappa_6 = 0$ in the ABJ theory as well, viz. there arises a unique spin chain operator to the six-loop dilatation operator. This then eliminates the possibility that, within maximal ranged interactions, parity non-conserving effect arises at six loops and beyond.

On the other hand, we suspect that the effect of parity non-conservation may show up at planar limit in some of the higher conserved charges $Q_n, \bar{Q}_n$ ($n \geq 3$). With indications from recent results of [31], we also expect that parity non-conserving effects will also arise from non-planar corrections. Given that there is no known examples of parity non-conserving yet integrable system, further understanding on this issue would be very rewarding.

8 Conclusions

In this paper, we studied the dilatation operator of $\mathcal{N} = 6$ Chern-Simons theory, paying attention to two pertinent issues that begins to arise from six loops and beyond: magnon spectrum and operator contents of the dilatation operator viewed as a spin chain Hamiltonian. The integrability together with the excitation symmetry plus the 2-loop results led to the unique prediction for the maximal shuffling terms to all orders.

We computed the maximal shuffling terms in the dilatation operator. We found that the coefficients of this term, which arise from so-called *homogeneous* diagrams, agree with the prediction of the integrability and the recursive property. We thus found that the situation of maximal shuffling interactions is exactly parallel to the situation in $\mathcal{N} = 4$ super-Yang-Mills theory. Despite the parallel, we also argued that the $\mathcal{N} = 6$ Chern-Simons theory is significantly different from the $\mathcal{N} = 4$ super Yang-Mills theory since there separately exist so-called *inhomogeneous* diagrams. These diagrams do not generate maximal shuffling terms but are still maximally-ranged. We showed that the *inhomogeneous* diagrams are not recursive and appears

to depend on the choice of infrared regularization.

To handle these difficulties, we adopted *ab initio* method of extracting the dilatation operator from two-point correlation functions of single-trace composite operator. In dual Type IIA string theory, this amounts to deriving time-evolution Hamiltonian of a single free string. The method was particularly convenient for extracting not only the spectrum but also the operator contents of the dilatation operator. By explicit computations, we determined the maximally-ranged interactions of the dilatation operator up to 6-loop order. We were able to compute pertinent Feynman diagrams by utilizing the remarkable integer-relation algorithm PSLQ. We found that, though details of Feynman diagrams contributing to the dilatation operator are very different, the operator contents and the recursive coefficients of the maximal-ranged interaction is identical to the dilatation operator in the $\mathcal{N} = 4$ super-Yang-Mills theory. This result is of course consistent with the integrability, which we consider as a highly nontrivial test for the $\mathcal{N} = 6$ ABJM theory.

We pointed out that extension of the results to the parity non-conserving $\mathcal{N} = 6$ ABJ theory is rather trivial, at least for the maximally-ranged interactions. One just replaces the 't Hooft coupling squared λ^2 of the $\mathcal{N} = 6$ ABJM theory by product of the two 't Hooft couplings $\lambda\bar{\lambda}$ of the $\mathcal{N} = 6$ ABJ theory. The resulting dilatation operator remains to be parity conserving.

In the above test, we assume that the pseudo-momentum coincides with the lattice momentum in the operator space. This assumption can be further tested computing the next-maximal shuffling coefficient $e_{6,4}$, which is predicted as $e_{6,4} = -32h_2$.

Recently, the coefficient h_2 was computed in [36]. Given that Ward identity was not verified to the order the computation is based on, the result of [36] needs to be checked independently. In particular, there is no first-principle understanding of its origin. One promising approach of the independent check would be the following. In Ref. [35], it was noted that $h(\lambda)$ should also be present as a renormalization factor in the central charges of the off-shell $[psu(2|2) \oplus psu(2|2)] \ltimes \mathbb{R}^{2,1}$ superalgebra. Any further understanding of this function $h(\lambda)$ such as renormalization of the central charges would be extremely interesting.

A Comparative calculation of inhomogeneous diagram

Below, for comparison with two-point function method, we shall illustrate a comparative calculation of a sample inhomogeneous diagram in operator-mixing method. Consider the inhomogeneous diagram in Fig. 3. The diagram has three skeleton vertices but, by reflection symmetry of the diagram, there are only two independent skeleton vertices. To control potential infrared divergences, it is necessary to inject nonzero momentum to the operator judiciously diagram by diagram. Here, consider injecting q at the top or bottom skeleton vertex. This is what we did for the homogeneous diagrams and found to yield an infrared finite result. For the skeleton 2-loop, which is actually elementary 6-loop, we find the contribution

$$\begin{aligned}\mathcal{B}_2^{\text{bare}} &= (-(2\pi)^2)^3 (-4)^3 C_3^2 G(1+\varepsilon, 1) G(3-\omega+\varepsilon, \varepsilon) \frac{1}{(4\pi)^{2\omega}} \frac{1}{(q^2)^{3\varepsilon}} \\ &= -\frac{1}{(4\pi)^3} \left[\frac{4\pi}{q^2} \right]^{3\varepsilon} \frac{1}{3! \varepsilon^3} \frac{[\Gamma(\frac{1}{2}-\frac{\varepsilon}{2})]^7 \Gamma(1+3\varepsilon)}{(\frac{1}{2}-\frac{3}{2}\varepsilon)(\frac{1}{2}+\frac{3}{2}\varepsilon)(\frac{1}{2}-\frac{7}{2}\varepsilon)\Gamma(\frac{1}{2}-\frac{7}{2}\varepsilon)}.\end{aligned}\quad (\text{A.1})$$

Along with lower-range diagrams $\mathcal{A}_0, \mathcal{A}_1$ in (3.19, 3.20), this contributes to the 6-loop part, $\mathcal{W}_6$, of $\ln I_{\text{bare}}(\varepsilon)$:

$$\mathcal{W}_6(\varepsilon) = \left[\mathcal{B}_2 - 2 \cdot \frac{1}{2} \mathcal{A}_0 \mathcal{A}_1 + \frac{1}{3!} \mathcal{A}_0^3 \right]^{\text{bare}} \cdot 4^3 \mathbb{O}_{6,6}^{\text{in}}. \quad (\text{A.2})$$

We relegate details of computation of the operator content to section 6 and focus on the coefficient of $\mathbb{O}_{6,6}^{\text{in}}$. By multiplicative renormalizability, the leading singularity of $\mathcal{W}_6$ must begin at order of $O(\varepsilon^{-1})$, viz. $\lim_{\varepsilon \rightarrow 0} \varepsilon \ln I_{\text{bare}}(\varepsilon)$ must be finite. For this diagram, we found

$$\mathcal{W}_6(\varepsilon) = \left[-\frac{1}{16} \varepsilon^{-3} - \frac{25+9\psi(1)}{48} \varepsilon^{-2} + O(\varepsilon^{-1}) \right] \cdot 4^3 \mathbb{O}_{6,6}^{\text{in}}. \quad (\text{A.3})$$

Alternatively, we may opt to inject momentum q at the middle skeleton vertex. In this case, we find

$$\begin{aligned}\mathcal{B}_2'^{\text{bare}} &= (-(2\pi)^2)^3 (-4)^3 C_3^2 G(1+\varepsilon, 1) G(2+\varepsilon-\omega, 1+\varepsilon) \frac{1}{(4\pi)^{2\omega}} \frac{1}{(q^2)^{3\varepsilon}} \\ &= \frac{1}{(4\pi)^3} \left[\frac{4\pi}{q^2} \right]^{3\varepsilon} \frac{1}{3 \varepsilon^3} \frac{[\Gamma(\frac{1}{2}-\frac{\varepsilon}{2})]^7 \Gamma(1+3\varepsilon)}{(\frac{1}{2}-\frac{3}{2}\varepsilon)^2 (\frac{1}{2}-\frac{7}{2}\varepsilon) \Gamma(\frac{1}{2}-\frac{7}{2}\varepsilon)}.\end{aligned}\quad (\text{A.4})$$

Hence the 6-loop part of the logarithm becomes

$$\begin{aligned}\mathcal{W}'_6(\epsilon) &= \left[\mathcal{B}'_2 - \mathcal{A}_0 \mathcal{A}_1 + \frac{1}{6} \mathcal{A}_0^3 \right]^{\text{bare}} \cdot 4^3 \mathbb{O}_{6,6}^{\text{in}} \\ &= \left[0 \cdot \epsilon^{-3} + \frac{1}{6} \epsilon^{-2} + O(\epsilon^{-1}) \right] \cdot 4^3 \mathbb{O}_{6,6}^{\text{in}}.\end{aligned}\tag{A.5}$$

The Feynman diagram ought to be infrared finite once independent momenta are injected to every external vertices. Unfortunately, the loop integral in this case is too complicated and do not permit all-loop resummation. So, we see that in both options the problem stems from non-analyticity as some of the injected momenta are taken to zero.

B Proof the operator identities (5.6) and (5.11)

To prove these two identities, we use the identity in (5.15) repeatedly. For (5.6), we first show the following identity:

$$\mathbb{P}_{17}\mathbb{P}_{35} - \mathbb{P}_{15}\mathbb{P}_{37} = \mathbb{P}_{13}\mathbb{P}_{35}\mathbb{P}_{57} + \mathbb{P}_{57}\mathbb{P}_{35}\mathbb{P}_{13} - \mathbb{P}_{13}\mathbb{P}_{57} - \mathbb{P}_{15} - \mathbb{P}_{37} + \mathbb{I}.\tag{B.1}$$

To show this, note that

$$\begin{aligned}\mathbb{P}_{17}\mathbb{P}_{35} - \mathbb{P}_{15}\mathbb{P}_{37} &= \left(\mathbb{P}_{15}\mathbb{P}_{57} + \mathbb{P}_{57}\mathbb{P}_{15} - \mathbb{P}_{15} - \mathbb{P}_{57} + \mathbb{I} \right) \mathbb{P}_{35} \\ &\quad - \mathbb{P}_{15} \left(\mathbb{P}_{35}\mathbb{P}_{57} + \mathbb{P}_{57}\mathbb{P}_{35} - \mathbb{P}_{35} - \mathbb{P}_{57} + \mathbb{I} \right) \\ &= -\mathbb{P}_{35}\mathbb{P}_{13}\mathbb{P}_{57} + \mathbb{P}_{57}\mathbb{P}_{35}\mathbb{P}_{13} - \mathbb{P}_{57}\mathbb{P}_{35} - \mathbb{P}_{15} + \mathbb{P}_{35} + \mathbb{P}_{15}\mathbb{P}_{57} \\ &= -\mathbb{P}_{35}\mathbb{P}_{13}\mathbb{P}_{57} + \mathbb{P}_{57}\mathbb{P}_{35}\mathbb{P}_{13} - \mathbb{P}_{57}\mathbb{P}_{35} - \mathbb{P}_{15} + \mathbb{P}_{35} \\ &\quad + \left(\mathbb{P}_{13}\mathbb{P}_{35} + \mathbb{P}_{35}\mathbb{P}_{13} - \mathbb{P}_{13} - \mathbb{P}_{35} + \mathbb{I} \right) \mathbb{P}_{57} \\ &= \mathbb{P}_{13}\mathbb{P}_{35}\mathbb{P}_{57} + \mathbb{P}_{57}\mathbb{P}_{35}\mathbb{P}_{13} - \mathbb{P}_{13}\mathbb{P}_{57} - \mathbb{P}_{15} - \mathbb{P}_{37} + \mathbb{I} \\ &\quad - \left(\mathbb{P}_{35}\mathbb{P}_{57} + \mathbb{P}_{57}\mathbb{P}_{35} - \mathbb{P}_{35} - \mathbb{P}_{57} - \mathbb{P}_{37} + \mathbb{I} \right) \\ &= \mathbb{P}_{13}\mathbb{P}_{35}\mathbb{P}_{57} + \mathbb{P}_{57}\mathbb{P}_{35}\mathbb{P}_{13} - \mathbb{P}_{13}\mathbb{P}_{57} - \mathbb{P}_{15} - \mathbb{P}_{37} + \mathbb{I},\end{aligned}\tag{B.2}$$

Here, we used (5.15) to replace $\mathbb{P}_{17}$ and $\mathbb{P}_{37}$ in the first line and the second $\mathbb{P}_{15}$ in the third line.

Next, we turn to the operator $\mathbb{O}_{1\sim 7}$:

$$\begin{aligned}&-2^{-3} \left[\mathbb{O}_{123}\mathbb{O}_{345}\mathbb{O}_{567} + \mathbb{O}_{567}\mathbb{O}_{345}\mathbb{O}_{123} \right] \\ &= (2\mathbb{P}_{13} - \mathbb{I})(2\mathbb{P}_{35} - \mathbb{I})(2\mathbb{P}_{57} - \mathbb{I}) + (2\mathbb{P}_{57} - \mathbb{I})(2\mathbb{P}_{35} - \mathbb{I})(2\mathbb{P}_{13} - \mathbb{I})\end{aligned}$$

$$\begin{aligned}
&= 8 \left(\mathbb{P}_{13} \mathbb{P}_{35} \mathbb{P}_{57} + \mathbb{P}_{57} \mathbb{P}_{35} \mathbb{P}_{13} + \mathbb{P}_{13} \mathbb{P}_{57} - \mathbb{P}_{15} - \mathbb{P}_{37} + \mathbb{I} \right) \\
&\quad + 4\mathbb{P}_{15} + 4\mathbb{P}_{37} - 4\mathbb{P}_{35} - 2\mathbb{I} \\
&= 8 \left(\mathbb{P}_{17} \mathbb{P}_{35} - \mathbb{P}_{15} \mathbb{P}_{37} \right) + 4\mathbb{P}_{15} + 4\mathbb{P}_{37} - 4\mathbb{P}_{35} - 2\mathbb{I} \\
&= 8 \left[-64\mathbb{O}_{6,6} + 80\mathbb{O}_{4,4} - 22\mathbb{O}_{2,2} + \frac{1}{4}\mathbb{I} \right], \tag{B.3}
\end{aligned}$$

which is the proof of the identity (5.6).

Finally, we turn to the identity in (5.11):

$$\begin{aligned}
\mathbb{O}_{1\sim 7} + \tilde{\mathbb{O}}_{1\sim 7} &= \mathbb{O}_{123} \left(\mathbb{O}_{345} \mathbb{O}_{567} + \mathbb{O}_{567} \mathbb{O}_{345} \right) + \left(\mathbb{O}_{345} \mathbb{O}_{567} + \mathbb{O}_{567} \mathbb{O}_{345} \right) \mathbb{O}_{123} \\
&= 2(\mathbb{I} - 2\mathbb{P}_{13})(-8)(\mathbb{I} - 2\mathbb{P}_{37}) + (-8)(\mathbb{I} - 2\mathbb{P}_{37})2(\mathbb{I} - 2\mathbb{P}_{13}) \\
&= 32(\mathbb{I} - 2\mathbb{P}_{17}). \tag{B.4}
\end{aligned}$$

C Derivation of $a_6(\varepsilon)$ and $\tilde{a}_6(\varepsilon)$

The diagram in (5) involves four 1-bubble and two 2-bubble propagators in total. The corresponding factors are $(C_2)^4(C_3)^2$. This then leads to the skeleton 4-loop diagram in Fig. 12. We assign momentum and the w -factor to each internal line as follows; k_1 and $w_1 = 2 - \omega$ for the upper-right line, $p - k_1 - k_2$ and $w_5 = 2 - \omega$ for the middle-right line, k_2 and $w_2 = 3 - 2\omega$ for the lower-right line, $k_3 - k_1$ and $w_7 = 1$ for the upper-center line, $k_4 - k_2$ and $w_8 = 1$ for the lower-center line, k_3 and $w_3 = 3 - 2\omega$ for the upper-left line, $p - k_3 - k_4$ and $w_6 = 2 - \omega$ for the middle-left line, k_4 and $w_4 = 2 - \omega$ for the lower-left line. One has then

$$a_6(\varepsilon) (I_\varepsilon)^7 (x^2 \pi)^{9-6\omega} = S \cdot \frac{1}{(4\pi)^{4\omega}} \cdot J_4(\varepsilon) \cdot (C_2)^4 (C_3)^2 \int \frac{d^{2\omega} p}{(2\pi)^{2\omega}} \frac{1}{(p^2)^{16-12\omega}} e^{ip \cdot x}, \tag{C.1}$$

where $S = (-4\pi^2)^3$ is the vertex and symmetry factors.

For the Fourier transform, we used the formula,

$$\int \frac{d^{2\omega} p}{(2\pi)^{2\omega}} \frac{1}{(p^2)^\alpha} e^{ip \cdot x} = \frac{\Gamma(\omega - \alpha)}{4^\alpha \pi^\omega \Gamma(\alpha)} \frac{1}{(x^2)^{\omega - \alpha}}. \tag{C.2}$$

This leads to the expression $a_6(\varepsilon)$ in (6.13).

The diagram in (7) involves two 1-bubble and three 2-bubble propagators in total. This leads to the skeleton 4-loop diagram in Fig. 12. We assign momentum and their w -factor to each internal line as follows; k_1 and $w_1 = 2 - \omega$ for the upper-right line, $p - k_1 - k_2$ and $w_5 = 3 - 2\omega$ for the middle-right line, k_2 and $w_2 = 2 - \omega$ for the lower-right line, $k_3 - k_1$ and $w_7 = 1$ for

the upper-center line, $k_4 - k_2$ and $w_8 = 1$ for the lower-center line, k_3 and $w_3 = 3 - 2\omega$ for the upper-left line, $p - k_3 - k_4$ and $w_6 = 1$ for the middle-left line, k_4 and $w_4 = 3 - 2\omega$ for the lower-left line. One has then

$$\tilde{a}_6(\epsilon) (I_\epsilon)^7 (x^2 \pi)^{9-6\omega} = S \cdot \frac{1}{(4\pi)^{4\omega}} \cdot J_5(\epsilon) \cdot (C_2)^2 (C_3)^3 \int \frac{d^{2\omega} p}{(2\pi)^{2\omega}} \frac{1}{(p^2)^{16-12\omega}} e^{ip \cdot x}. \quad (\text{C.3})$$

This leads to the expression $a_6(\epsilon)$ in (6.20).

D Evaluation of the integrals $J_1(\epsilon)$, $J_4(\epsilon)$ and $J_5(\epsilon)$

In this appendix, we evaluate the higher order terms of the two-loop integral $J_1(\epsilon)$ and two four-loop integrals, $J_4(\epsilon)$ and $J_5(\epsilon)$ in the section 6. It is difficult to find their analytic forms in a direct manner. We first numerically evaluate the integrals and then find the corresponding expressions consisting of transcendental numbers. There exists PSLQ algorithm[39] which is quite useful in finding such an analytic form from numerical data. For the numerical evaluation, we use the Mathematica packages—MB[40, 41] and AMBRE[42]. To find the corresponding analytic expression, we use the package PSLQ.nb[43], which is a Mathematica implementation of the PSLQ algorithm.

Since these methods are based on the Mellin-Barnes representation of Feynman integrals, we cast the integrals into the form:

$$\begin{aligned} K_5(w_1, w_2, w_3, w_4, w_5) &= \int \frac{dz_1}{2\pi i} \int \frac{dz_2}{2\pi i} \frac{\Gamma(-z_1) \Gamma(\omega - w_{25} - z_1) \Gamma(\omega - w_1 + z_1)}{\Gamma(w_1 - z_1)} \\ &\quad \otimes \frac{\Gamma(-z_2) \Gamma(\omega - w_{35} - z_2) \Gamma(\omega - w_4 + z_2)}{\Gamma(w_4 - z_2)} \\ &\quad \otimes \frac{\Gamma(-\omega + w_{14} - z_{12}) \Gamma(-\omega + w_{235} + z_1 + z_2) \Gamma(w_5 + z_{12})}{\Gamma(w_2) \Gamma(w_3) \Gamma(w_5) \Gamma(w_{235}) \Gamma(2\omega - w_{235}) \Gamma(2\omega - w_{14} + z_{12})}. \end{aligned} \quad (\text{D.1})$$

with $w_{12\dots} = w_1 + w_2 + \dots$ and $z_{12\dots} = z_1 + z_2 + \dots$. Direct application of these packages yields the following result:

$$J_1(\epsilon) = K_5(2 - \omega, 3 - 2\omega, 2 - \omega, 3 - 2\omega, 1) = \frac{\alpha_{J_1}^{-1}}{\epsilon} \left[1 + \alpha_{J_1}^0 \epsilon + \alpha_{J_1}^1 \epsilon^2 + O(\epsilon^3) \right], \quad (\text{D.2})$$

where we have found $\alpha_{J_1}^{-1} = -\frac{2}{3\pi}$ and $\alpha_{J_1}^0 = 13 + \psi(\frac{1}{2})$ as reported in [35]. The numerical value of $\alpha_{J_1}^1$ is obtained as

$$4\alpha_{J_1}^1 = 309.7165844821997330276736227359\dots \quad (\text{D.3})$$

By the PSLQ algorithm, we matched this numerical result as a linear combination of 1 , π^2 , $\psi(\frac{1}{2})$ and $\psi^2(\frac{1}{2})$ under the condition that their coefficients are rational numbers. This basis follows from requiring that $e_{4,4}$ is a rational number. This leads to the unique set of fractional coefficients:

$$4\alpha_{J_1}^1 = 488 - \frac{17}{2}\pi^2 + 52\psi(\frac{1}{2}) + 2\psi^2(\frac{1}{2}). \quad (\text{D.4})$$

Note that the number of significant digits in this numerical value is 30 and the difference between these two expression is less than 10^{-30} . We have checked the other numbers, $\alpha_{J_1}^{-1}$ and $\alpha_{J_1}^0$ to the same accuracy.

The four-loop integrals $K_8(w_1, \dots, w_8)$ in (6.14) can be evaluated in a similar way. Its Mellin-Barnes representation is given as

$$I_8(w_1, \dots, w_8) = \int \frac{dz_1}{2\pi i} \cdots \int \frac{dz_8}{2\pi i} \frac{N}{D} \quad (\text{D.5})$$

where

$$\begin{aligned} N = & \left[\prod_{n=1}^8 \Gamma(-z_n) \right] \Gamma(w_3 + z_{246}) \Gamma(w_7 + z_{235}) \Gamma(\omega/2 + z_{38}) \Gamma(\omega/2 - w_{48} - z_1) \\ & \otimes \Gamma(\omega/2 - w_6 - z_1) \Gamma(\omega - w_{3467} - z_{234}) \Gamma(\omega - w_{3678} - z_{256}) \\ & \otimes \Gamma(3\omega/2 - w_{3346778} - z_{1223456}) \Gamma(3\omega/2 - w_{234678} - z_{23457}) \\ & \otimes \Gamma(-2\omega + w_{12345678} + z_{47}) \Gamma(3\omega/2 - w_{2345678} - z_{23468}) \\ & \otimes \Gamma(2\omega - w_{12345678} - z_{3478}) \Gamma(-3\omega/2 + w_{2345678} + z_{23478}) \\ & \otimes \Gamma(-\omega + w_{234678} + z_{2345678}) \Gamma(-\omega + w_{34678} + z_{123456}) \end{aligned} \quad (\text{D.6})$$

and

$$\begin{aligned} D = & \Gamma(w_3) \Gamma(w_5) \Gamma(w_6) \Gamma(w_7) \Gamma(w_8) \Gamma(\omega - w_{468}) \Gamma(w_5 - z_5) \Gamma(-z_{38}) \\ & \otimes \Gamma(3\omega/2 - w_{34678} - z_1) \Gamma(2\omega - w_{2345678} - z_{234}) \\ & \otimes \Gamma(2\omega - w_{33466778} - z_{223456}) \Gamma(-\omega + w_{234678} + z_{23456}) \\ & \otimes \Gamma(5\omega/2 - w_{12345678} - z_{47}) \Gamma(-3\omega/2 + w_{12345678} + z_{3478}). \end{aligned} \quad (\text{D.7})$$

The $J_4(\epsilon)$ and $J_5(\epsilon)$, respectively, in (6.16) and (6.21) are defined with help of K_8 . By numerical computations, we find that $J_4(\epsilon)$ has the expansion,

$$J_4(\epsilon) = \frac{0.012008436579832 \dots}{\epsilon^2} \left[1 + (50.0126265 \dots) \frac{\epsilon}{2} + (360.321 \dots) \epsilon^2 \right]. \quad (\text{D.8})$$

By the PSLQ algorithm, this can be converted to the following expression

$$J_4(\epsilon) = \frac{16}{135\pi^2} \frac{1}{\epsilon^2} \left[1 + \left(\frac{434}{15} + 2\psi\left(\frac{1}{2}\right) \right) \epsilon + \left(\frac{117301}{225} - \frac{67}{12}\pi^2 + \frac{868}{15}\psi\left(\frac{1}{2}\right) + 2\psi^2\left(\frac{1}{2}\right) \right) \epsilon^2 \right]. \quad (\text{D.9})$$

The first two numbers can be calculated analytically from the requirement of the multiplicative renormalizability. These agree with the numerical values computed as above. In the last number, the coefficients of π^2 , $\psi(\frac{1}{2})$ and $\psi^2(\frac{1}{2})$ can be fixed by the assumption that $e_{6,6}$ is a fractional number. Then the remaining fraction agrees with the numerical value to six significant digits.

The last integral $J_5(\epsilon)$ is found to be

$$J_5(\epsilon) = \frac{0.11851851851\dots}{\epsilon} \left[1 + (21.8926\dots)\epsilon + (571.233\dots)\frac{\epsilon^2}{2} \right]. \quad (\text{D.10})$$

This is equivalent to the following expression:

$$J_5(\epsilon) = \frac{16}{135\epsilon} \left[1 + \left(\frac{733}{30} + \psi(1) + \psi\left(\frac{1}{2}\right) \right) \epsilon + \left(\frac{177587}{225} - \frac{61}{6}\pi^2 + \frac{733}{15}[\psi(1) + \psi(\frac{1}{2})] + [\psi(1) + \psi(\frac{1}{2})]^2 \right) \frac{\epsilon^2}{2} \right]. \quad (\text{D.11})$$

We again checked the first two numbers from the renormalization of the underlying field theory. The last number is again determined in an analogous manner to (D.9) and agrees with the numerical value up to six significant digits.
